COMPONENTS OF SPACES OF CURVES WITH CONSTRAINED CURVATURE ON FLAT SURFACES

Nicolau C. Saldanha and Pedro Zühlke
COMPONENTS OF SPACES OF CURVES WITH CONSTRAINED CURVATURE ON FLAT SURFACES

NICOLAU C. SALDANHA AND PEDRO ZÜHLKE

Let $S$ be a complete flat surface, such as the Euclidean plane. We obtain direct characterizations of the connected components of the space of all curves on $S$ which start and end at given points in given directions, and whose curvatures are constrained to lie in a given interval, in terms of all parameters involved. Many topological properties of these spaces are investigated. Some conjectures of L. E. Dubins are proved.

0. Introduction

To abbreviate the notation, we shall identify $\mathbb{R}^2$ with $\mathbb{C}$ throughout. A curve $\gamma : [0, 1] \to \mathbb{C}$ is called regular if its derivative is continuous and never vanishes. Its unit tangent is then defined as

$$t_\gamma : [0, 1] \to \mathbb{S}^1, \quad t_\gamma(t) = \frac{\dot{\gamma}(t)}{|\dot{\gamma}(t)|}.$$  

Lifting $\gamma$ to the unit tangent bundle $UT\mathbb{C} \equiv \mathbb{C} \times \mathbb{S}^1$, we obtain its frame

$$\Phi_\gamma : [0, 1] \to \mathbb{C} \times \mathbb{S}^1, \quad \Phi_\gamma(t) = (\gamma(t), t_\gamma(t)).$$
Let \( P = (p, w), Q = (q, z) \in \mathbb{C} \times S^1 \) and consider the spaces of curves

\[
S(P, Q) = \{ \gamma : [0, 1] \to \mathbb{C} : \gamma \text{ is regular, } \Phi_\gamma(0) = P \text{ and } \Phi_\gamma(1) = Q \},
\]

endowed with the \( C^r \) and \( C^{r-1} \) topologies, respectively (\( 1 \leq r \in \mathbb{N} \)). In 1956, S. Smale proved that the map

\[
\Phi : S(P, Q) \to \Omega UT\mathbb{C}(P, Q), \quad \gamma \mapsto \Phi_\gamma,
\]
is a weak homotopy equivalence (that is, it induces isomorphisms on homotopy groups). Actually, Smale’s theorem [1958, Theorem C] is much more general in that it holds for any manifold, not just \( \mathbb{C} \). Using standard results on Banach manifolds which were discovered later, one can conclude that the spaces in (2) are in fact homeomorphic, and that the value of \( r \) is unimportant.

Given a regular plane curve \( \gamma \), an argument of \( t_\gamma \) is a continuous function \( \theta_\gamma : [0, 1] \to \mathbb{R} \) such that \( t_\gamma = e^{i\theta_\gamma} \). The total turning of \( \gamma \) is defined to be \( \theta_\gamma(1) - \theta_\gamma(0) \); note that this is independent of the choice of \( \theta_\gamma(0) \). It is easy to see that \( \Omega UT\mathbb{C}(P, Q) \) is homotopy equivalent to \( \Omega S^1(w, z) \). The latter possesses infinitely many connected components, one for each \( \theta_1 \) satisfying \( e^{i\theta_1} = z\bar{w} = zw^{-1} \), all of which are contractible. Therefore, the components of \( S(P, Q) \) are all contractible as well, and two curves in \( S(P, Q) \) lie in the same component if and only if they have the same total turning. This generalizes the Whitney–Graustein theorem [Whitney 1937, Theorem 1] to nonclosed curves.

The main purpose of this work is to investigate the topology of subspaces of \( S(P, Q) \) obtained by imposing constraints on the curvature of the curves.

\[\text{(0.1) Definition.} \quad \text{Suppose } -\infty \leq \kappa_1 < \kappa_2 \leq +\infty \text{ and } r \in \{2, 3, \ldots, \infty\}. \text{ For } P = (p, w), Q = (q, z) \in \mathbb{C} \times S^1, \text{ define } \mathcal{C}^{\kappa_2}_{\kappa_1}(P, Q) \text{ to be the set of all } C^r \text{ regular curves } \gamma : [0, 1] \to \mathbb{C} \text{ such that }\]

(i) \( \Phi_\gamma(0) = P \) and \( \Phi_\gamma(1) = Q \);

(ii) the curvature \( \kappa_\gamma \) of \( \gamma \) satisfies \( \kappa_1 < \kappa_\gamma(t) < \kappa_2 \) for each \( t \in [0, 1] \).

Let this set be furnished with the \( C^r \) topology.

Condition (i) means that \( \gamma \) starts at \( p \) in the direction of \( w \) and ends at \( q \) in the direction of \( z \). In this notation, \( S(P, Q) \) becomes \( \mathcal{C}^{(+\infty)}_{(-\infty)}(P, Q) \). The connected components of \( \mathcal{C}^{(+\kappa_0)}_{(-\kappa_0)}(P, Q) \) (\( \kappa_0 > 0 \)) were first studied by L. E. Dubins [1961]. His main result (Theorem 5.3, slightly rephrased) implies that there may exist curves with the same total turning which are not homotopic within this space.

**Theorem (Dubins).** Suppose \( x > 0 \) and \( Q_x = (x, 1), O = (0, 1) \in \mathbb{C} \times S^1 \). Let \( \eta \in \mathcal{C}^{(1)}_{(-1)}(O, Q_x) \) be the line segment parametrized by \( \eta(t) = xt \). Then the con-
catenation of \( \eta \) with a figure eight curve lies in the same connected component of \( \mathcal{C}^{+1}_{-1}(O, Q_x) \) as \( \eta \) if and only if \( x > 4 \).

Here a “figure eight” curve means any closed curve of total turning 0 whose curvature takes values in \((-1, 1)\), such as the one depicted in Figure 7(d).

Naturally, we always have the following decomposition of \( \mathcal{C}^{k_2}_{k_1}(P, Q) \) into closed-open subspaces:

\[
\mathcal{C}^{k_2}_{k_1}(P, Q) = \bigcup_{\theta_1} \mathcal{C}^{k_2}_{k_1}(P, Q; \theta_1),
\]

where \( \mathcal{C}^{k_2}_{k_1}(P, Q; \theta_1) \) consists of those curves in \( \mathcal{C}^{k_2}_{k_1}(P, Q) \) which have total turning equal to \( \theta_1 \) and the union is over all \( \theta_1 \in \mathbb{R} \) satisfying \( e^{i\theta_1} = z\bar{w} \).

If \( k_1k_2 \geq 0 \), it will be shown that each \( \mathcal{C}^{k_2}_{k_1}(P, Q; \theta_1) \) is either empty or a contractible connected component of \( \mathcal{C}^{k_2}_{k_1}(P, Q) \).\(^1\) If \( k_1k_2 < 0 \), then \( \mathcal{C}^{k_2}_{k_1}(P, Q; \theta_1) \) is never empty, and it is a contractible connected component provided that \( |\theta_1| \geq \pi \). However, the remaining subspace \( \mathcal{C}^{k_2}_{k_1}(P, Q; \theta_1) \) with \( |\theta_1| < \pi \) may not be contractible, nor even connected, as implied by Dubins’ theorem. It turns out that one can obtain simple and explicit characterizations of its components in terms of \( \kappa_1, \kappa_2, P \) and \( Q \) by using a homeomorphism with a space of the form \( \mathcal{C}^{+1}_{-1}(P_0, Q_0; \theta_1) \) and an elementary geometric construction (see Figure 1).

This paper is close in spirit to Dubins’ [1961], and some of his conjectures will be settled; it is not assumed, however, that the reader is familiar with his work. In the sequel to this article [Saldanha and Zühlke 2015], we determine the homotopy type of \( \mathcal{C}^{k_2}_{k_1}(P, Q) \). Granted the results described above, the only remaining task is the determination of the homotopy type of the exceptional subspace \( \mathcal{C}^{k_2}_{k_1}(P, Q; \theta_1) \subset \mathcal{C}^{k_2}_{k_1}(P, Q) \) with \( |\theta_1| < \pi \) (\( k_1k_2 < 0 \)) containing the curves in the latter of least total turning. It is proved in [Saldanha and Zühlke 2015] that this subspace may be homotopy equivalent to an \( n \)-sphere for any \( n \in \{0, 1, \ldots, \infty\} \) (recall that \( \mathbb{S}^{\infty} \) is contractible). The value of \( n \) can be determined in terms of all parameters by first reducing to the case where \( \kappa_1 = -1, \kappa_2 = +1 \) through the homeomorphism mentioned above, and then using a construction extending the one depicted in Figure 1 (which only tells whether \( n = 0 \) or not).

**Outline of the sections.** Many useful constructions, such as the catenation of elements of \( \mathcal{C}^{k_2}_{k_1}(P, Q) \) and \( \mathcal{C}^{k_2}_{k_1}(Q, R) \), yield curves which need not be of class \( C^2 \). To avoid having to smoothen curves all the time, we work with curves which have a continuously varying unit tangent at all points, but whose curvatures are defined only almost everywhere. The resulting spaces, denoted by \( \mathcal{L}^{k_2}_{k_1}(P, Q) \), are defined in Section 1, where it will also be seen that the set inclusion \( \mathcal{C}^{k_2}_{k_1}(P, Q) \rightarrow \mathcal{L}^{k_2}_{k_1}(P, Q) \) is a homotopy equivalence with dense image and that these spaces are homeomorphic.

---

\(^1\)In determining the sign of \( k_1k_2 \), we adopt the convention that \( 0(\pm\infty) = 0 \).
Figure 1. Let \( \theta_1 \in \mathbb{R} \) be fixed, \( z = e^{i\theta_1} \) and \( Q = (q, z) \). Then \( C_{1,-1}(Q; \theta_1) \) is disconnected if and only if \( |\theta_1| < \pi \) and \( q \) lies in the gray region. The region contains the arc of circle of radius 4, but not the arcs of circle of radius 2. Figure (a) depicts the case \( \theta_1 \in [0, \pi) \), and (b) the case \( \theta_1 \in (-\pi, 0] \) (here \( \theta_1 \approx \pm 26^\circ \)). The theorem of Dubins stated above corresponds to the case where \( \theta_1 = 0 \) and \( q \in \mathbb{R} \).

Let \( O = (0, 1) \in \mathbb{C} \times \mathbb{S}^1 \) denote the canonical element of UT\( C \), and let us denote \( \mathcal{C}_{\kappa_1 \kappa_2}(O, Q) \) simply by \( \mathcal{C}_{\kappa_2}(Q) \). Using Euclidean motions, dilatations and a construction called normal translation (see Figure 2 on p. 200), we obtain in (2.4) an explicit homeomorphism between any space \( \mathcal{C}_{\kappa_1}(P_0, Q_0) \) and a space of one of the following types: \( \mathcal{C}_0^{+\infty}(Q) \), \( \mathcal{C}_1^{+\infty}(Q) \) or \( \mathcal{C}_{1,-1}^{+\infty}(Q) \), according to whether \( \kappa_1 \kappa_2 = 0 \), \( \kappa_1 \kappa_2 > 0 \) or \( \kappa_1 \kappa_2 < 0 \), respectively. Moreover, this homeomorphism preserves the total turning of curves up to sign. Among these three, \( \mathcal{C}_{1,-1}^{+\infty}(Q) \) has the most interesting topological properties.

We call a regular curve \( \gamma : [0, 1] \to \mathbb{C} \) condensed, critical or diffuse, according to whether its amplitude

\[
\omega = \sup_{t \in [0,1]} \theta_\gamma(t) - \inf_{t \in [0,1]} \theta_\gamma(t)
\]

satisfies \( \omega < \pi \), \( \omega = \pi \) or \( \omega > \pi \), respectively. Let \( Q = (q, z) \in \mathbb{C} \times \mathbb{S}^1 \) and \( \theta_1 \) be such that \( e^{i\theta_1} = z \). Let \( \mathcal{U}_c \subset \mathcal{C}_{1,-1}^{+\infty}(Q; \theta_1) \) (resp. \( \mathcal{U}_d \subset \mathcal{C}_{1,-1}^{+\infty}(Q; \theta_1) \)) denote the subspace consisting of all condensed (resp. diffuse) curves. Both are open and
$\mathcal{U}_d \neq \emptyset$, since we may always concatenate a curve in $\mathcal{C}_{-1}^{+1}(Q; \theta_1)$ with a curve of total turning $0$ (an eight curve, as in Figure 7(e) on p. 218). Clearly, $\mathcal{U}_c$ must be empty if $|\theta_1| \geq \pi$, but it may also be empty otherwise, depending on $Q$. We determine exactly when this occurs in Section 3.

A condensed curve may be viewed as the graph of a function with respect to some axis. This leads to a direct, albeit involved, proof that $\mathcal{U}_c$ is contractible when nonempty. In fact, if the curvatures are allowed to be discontinuous and to take values in the closed interval $[-1, 1]$, then one can exhibit a contraction of the subspace of condensed curves to the unique curve of minimal length (Dubins path) in the corresponding space. This is also done in Section 3.

In Section 4, an indirect proof that $\mathcal{U}_c$ is contractible is obtained. If $\gamma$ is diffuse, then we can “graft” straight line segments onto $\gamma$, as illustrated in Figure 8, p. 223. Such a segment can be deformed so that in the end an eight curve of large radius traversed $n$ times has been attached to it. These eights are then spread along the curve, as in Figure 7(f). If $n \in \mathbb{N}$ is large enough, then the whole process can be carried out within $\mathcal{C}_{-1}^{+1}(Q)$. The result is a curve whose curvature is uniformly small, and hence easily deformable.

In Section 5 we determine when the set $\mathcal{T}$ of all critical curves in $\mathcal{C}_{-1}^{+1}(Q; \theta_1)$ is empty. The main result in this section is that $\mathcal{T} = \partial \mathcal{U}_c = \partial \mathcal{U}_d$. When $\mathcal{T} \neq \emptyset$, a finer analysis of how $\partial \mathcal{U}_c$ and $\partial \mathcal{U}_d$ fit together is required to determine the homeomorphism class of $\mathcal{C}_{-1}^{+1}(Q; \theta_1)$. This problem will be treated in [Saldanha and Zühlke 2015].

In (6.1) we obtain various characterizations of the connected components of $\mathcal{C}_{-1}^{+1}(Q; \theta_1)$. Perhaps the simplest one is the following: this space is disconnected if and only if $|\theta_1| < \pi$ and $q$ lies in the region illustrated in Figure 1, or, equivalently, its subset $\mathcal{T}$ is empty, but $\mathcal{U}_c$ is not. In this case, it has exactly two components, $\mathcal{U}_c$ and $\mathcal{U}_d$, which are contractible. As mentioned previously, this is sufficient to determine explicitly the components of any space $\mathcal{C}_{k_1}^{k_2}(P_0, Q_0)$ with $k_1k_2 < 0$.

In Section 7, it is established that when $k_1k_2 \geq 0$, the space $\mathcal{C}_{k_1}^{k_2}(P, Q)$ has one connected component for each realizable total turning, and they are all contractible. The set of possible total turnings can be described in terms of all parameters using normal translation and elementary geometry. The detailed solution to this problem is not carried out to shorten the paper, but it can be found in the earlier unpublished version [Saldanha and Zühlke 2014].

In Section 8 these results are extended to spaces of curves with constrained curvature on any complete flat surface $S$ (orientable or not) using the fact that if $S$ is connected then it must be the quotient of $\mathbb{C}$ by a group of isometries. Even though we have imposed that the curvatures should lie in an open interval, the main results obtained here have analogues for spaces (defined in Section 1) where the curvature is constrained to lie in $[\kappa_1, \kappa_2]$. For $\kappa_1 = -\kappa_2$, this is the class
with which Dubins actually worked [1957; 1961]. The necessary modifications in the statements and proofs are sketched in Section 9, where we also prove some conjectures appearing in [Dubins 1961] and discuss a few additional conjectures on curves of minimal length.

**Related work.** The problem treated here and in [Saldanha and Zühlke 2015] for flat surfaces can be generalized to any smooth (or even $C^2$) surface $S$ equipped with a Riemannian metric: if $u$, $v$ are elements of its unit tangent bundle $UTS$, then one can study the space $\mathcal{C}S_{\kappa_1}^{\kappa_2}(u, v)$ of curves on $S$ whose lift to $UTS$ joins $u$ to $v$ and whose geodesic curvature takes values in $(\kappa_1, \kappa_2)$. When $S$ is nonorientable, only the unsigned curvature makes sense, so in this case we require that $\kappa_2 = -\kappa_1 > 0$ (cf. Section 8 below). This topic is largely unexplored, and even the problem of determining when $\mathcal{C}S_{\kappa_1}^{\kappa_2}(u, v) \neq \emptyset$ is open (and probably difficult). The topology of these spaces is very closely related to the geometry of $S$.

A special case which has been more intensively studied is that of the space of nondegenerate curves on $S$, i.e., curves of nonvanishing curvature. In our notation, this corresponds to $\mathcal{C}S_0^{+\infty}(u, v) \sqcup \mathcal{C}S_0^{-\infty}(u, v)$. There is also an obvious generalization to higher-dimensional manifolds, obtained by replacing the (geodesic) curvature by the generalized curvature of a curve $\gamma : [0, 1] \to M^n$. To say that the latter does not vanish is equivalent to requiring that the first $n$ (covariant) derivatives of $\gamma$ at $\gamma(t)$ span the tangent space to $M$ at this point for each $t \in [0, 1]$. Some papers treating this problem, especially for spaces of closed curves on the simplest manifolds, such as $\mathbb{R}^n$, $\mathbb{S}^n$ or $\mathbb{R}P^n$, include [Anisov 1998; Feldman 1968; 1971, Khesin and Shapiro 1992; 1999, Little 1970; Mostovoy and Sadykov 2012; Saldanha 2015; Saldanha and Shapiro 2012; Shapiro and Shapiro 1991, Shapiro 1993]. Most of these are concerned with obtaining characterizations of the connected components of the corresponding spaces.

In [Saldanha 2015], the homotopy type of spaces of (not necessarily closed) nondegenerate curves on $\mathbb{S}^2$ is determined, and in [Saldanha and Zühlke 2013], the connected components of spaces of closed curves on $\mathbb{S}^2$ with curvature in an arbitrary interval $(\kappa_1, \kappa_2)$ are characterized. In the sequel [Saldanha and Zühlke 2015], we determine the homotopy type of $\mathcal{C}S_{\kappa_1}^{\kappa_2}(u, v)$ for any flat surface $S$ in terms of $\kappa_1, \kappa_2$ and $u, v \in UTS$. Many of the ideas appearing in the present paper (normal translation, diffuse vs. condensed, grafting, curvature spreading, etc.) appear in [Saldanha 2015] or [Saldanha and Zühlke 2013] in some form as well, although sometimes the connection is only heuristic.

### 1. Spaces of plane curves

**Basic terminology.** Let $\gamma : [a, b] \to \mathbb{C}$ be a regular curve. The unit normal $n = n_\gamma : [a, b] \to \mathbb{S}^1$ is given by $n = it$, where $i \in \mathbb{C}$ denotes the imaginary unit and
\( \mathbf{t} = \mathbf{t}_\gamma \) is the unit tangent to \( \gamma \). The arc-length parameter \( s \) of \( \gamma \) is defined by

\[
s(t) = \int_a^t |\dot{\gamma} (\tau)| \, d\tau \quad (t \in [a, b]),
\]

and \( L = \int_a^b |\dot{\gamma}(\tau)| \, d\tau \) is the length of \( \gamma \). Assuming \( \gamma \) is twice differentiable, its curvature \( \kappa = \kappa_\gamma \) is given by

\[
\kappa(s) = \langle \mathbf{t}'(s), \mathbf{n}(s) \rangle \quad (s \in [0, L]).
\]

In terms of a general parameter,

\[
\kappa = \frac{1}{|\dot{\gamma}|} \langle \dot{\mathbf{i}}, \mathbf{n} \rangle = \frac{1}{|\dot{\gamma}|^2} \langle \ddot{\gamma}, \mathbf{n} \rangle = \frac{\det(\dot{\gamma}, \ddot{\gamma})}{|\dot{\gamma}|^3}.
\]

(We denote derivatives with respect to arc-length by a ' (prime) and derivatives with respect to other parameters by a ' (dot).) Notice that the curvature at each point is not altered by an orientation-preserving reparametrization of the curve, while its sign changes if the reparametrization is orientation-reversing. It follows from (3) that if \( \theta_\gamma : [0, L] \to \mathbb{R} \) is an argument of \( \mathbf{t} \), then

\[
\kappa(s) = \theta_\gamma'(s).
\]

The following example illustrates one reason why it is more convenient to require that curvatures lie in an open interval, as in (0.1).

(1.1) Example. Consider the space of all \( C^2 \) regular curves \( \gamma : [0, 1] \to \mathbb{C} \) whose curvatures are restricted to lie in \([-1, 1]\) and which satisfy \( \Phi_\gamma(0) = (1, i) \), \( \Phi_\gamma(1) = (i, -1) \), where we have identified \( UT\mathbb{C} \) with \( \mathbb{C} \times S^1 \). The arc \( \alpha \) of the unit circle given by \( t \mapsto \exp(\pi it/2) \) \( (t \in [0, 1]) \) is a curve in this space. In fact, it is not hard to see that \( \alpha \) is an isolated point; i.e., its connected component does not contain any other curve.

In contrast, the spaces \( C^k_{k_i}(P, Q)^r \) are Banach manifolds (for \( r \neq \infty \)). Still, some useful constructions, such as the concatenation of curves, lead out of this class of spaces. To avoid having to smoothen curves all the time, we shall work with another class of spaces, which possess the additional advantage of being Hilbert manifolds.

**The group structure of \( UT\mathbb{C} \).** The group of all orientation-preserving isometries of \( \mathbb{C} \) (i.e., proper Euclidean motions) acts simply transitively on \( UT\mathbb{C} \). An element of this group is thus uniquely determined by where it maps \( (0, 1) \in UT\mathbb{C} \), and may be identified with this image. Therefore, \( UT\mathbb{C} \) carries a natural Lie group structure as a semidirect product \( \mathbb{C} \rtimes S^1 \), wherein the operation is

\[
(p, w) \cdot (q, z) = (p + wq, wz) \quad (p, q \in \mathbb{C}, \, w, z \in S^1).
\]
Accordingly, viewed as a one-parameter family of Euclidean motions, the frame $\Phi_\gamma$ of a regular curve $\gamma : [0, 1] \to \mathbb{C}$ operates on $\mathbb{C}$ through

$$\Phi_\gamma(t)a = \gamma(t) + t\gamma'(t) \quad (a \in \mathbb{C}, \ t \in [0, 1]).$$

If we identify the Lie algebra of $UT\mathbb{C}$ with $\mathbb{C} \times \mathbb{R}$, then the bracket operation is given by

$$[(a, \theta), (b, \varphi)] = (i(\theta b - \varphi a), 0) \quad (a, b \in \mathbb{C}, \theta, \varphi \in \mathbb{R}).$$

We can also realize $UT\mathbb{C}$ as a matrix group if we identify

$$P = (p, w) \text{ with } \begin{pmatrix} \cos \theta & -\sin \theta & x \\ \sin \theta & \cos \theta & y \\ 0 & 0 & 1 \end{pmatrix}, \quad \text{where } p = x + iy, \ w = e^{i\theta}. $$

Then $\Phi_\gamma$ corresponds to the map

$$\Phi_\gamma : [0, 1] \to GL_3, \quad \Phi_\gamma(t) = \begin{pmatrix} \cos \theta_\gamma(t) & -\sin \theta_\gamma(t) & \gamma_1(t) \\ \sin \theta_\gamma(t) & \cos \theta_\gamma(t) & \gamma_2(t) \\ 0 & 0 & 1 \end{pmatrix},$$

where $\theta_\gamma : [0, 1] \to \mathbb{R}$ is an argument of $t_\gamma$ and $\gamma(t) = \gamma_1(t) + i\gamma_2(t)$. Moreover, under this identification the Lie algebra $\mathfrak{a}$ of $UT\mathbb{C}$ becomes a subalgebra of $\mathfrak{gl}_3$ generated by

$$A = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \text{and} \quad C = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}. $$

The expression for the bracket in (7) can be easily derived from this.

**Spaces of admissible curves.** Suppose now that $\gamma : [0, 1] \to \mathbb{C}$ is not only regular, but also smooth. Let $\kappa$ denote its curvature and $\sigma = |\gamma'|$ its speed. Using (5), we deduce that

$$\dot{\Phi}_\gamma = |\dot{\gamma}| \begin{pmatrix} -\kappa \sin \theta_\gamma & -\kappa \cos \theta_\gamma & \cos \theta_\gamma \\ \kappa \cos \theta_\gamma & -\kappa \sin \theta_\gamma & \sin \theta_\gamma \\ 0 & 0 & 0 \end{pmatrix} = \Phi_\gamma \Lambda_\gamma, \quad \text{where } \Lambda_\gamma = \sigma \begin{pmatrix} 0 & -\kappa & 1 \\ \kappa & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}. $$

Let $\mathfrak{h} \subset \mathfrak{a}$ denote the half-plane

$$\mathfrak{h} = \{aA + bB : a \in \mathbb{R}, \ b > 0\}. $$

The map $\Lambda_\gamma : [0, 1] \to \mathfrak{h}$ is called the logarithmic derivative of $\gamma$. The crucial observation for us is that $\Phi_\gamma$ (and hence $\gamma$) is uniquely determined as the solution

---

$^2$Notice that the first column of $\Phi_\gamma$ gives the coordinates of $t_\gamma$, the second the coordinates of $n_\gamma$ and the third the coordinates of $\gamma$. This justifies our terminology “frame” for $\Phi_\gamma$. 
of an initial value problem

(11) $\Phi(0) = P \in UT\mathbb{C}$, \quad $\dot{\Phi} = \Phi \Lambda$, \quad where $\Lambda : [0, 1] \to \mathfrak{h}$, $\Lambda = \sigma \begin{pmatrix} 0 & -\kappa & 1 \\ \kappa & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$.

Equivalently, $\gamma$ is uniquely determined by $P = \Phi_\gamma(0)$ and the pair of functions $\kappa : [0, 1] \to \mathbb{R}$ and $\sigma : [0, 1] \to \mathbb{R}^+$. Our preferred class of spaces is obtained by relaxing the requirements that $\sigma$ and $\kappa$ be smooth.

Let $h = h_{0, +\infty} : (0, +\infty) \to \mathbb{R}$ be the smooth diffeomorphism

$$h(t) = t - t^{-1}.$$ 

More generally, for each pair $\kappa_1 < \kappa_2 \in \mathbb{R}$, let $h_{\kappa_1, \kappa_2} : (\kappa_1, \kappa_2) \to \mathbb{R}$ be the smooth diffeomorphism

$$h_{\kappa_1, \kappa_2}(t) = (\kappa_1 - t)^{-1} + (\kappa_2 - t)^{-1},$$

and, similarly, set

$$h_{-\infty, +\infty} : \mathbb{R} \to \mathbb{R}, \quad h_{-\infty, +\infty}(t) = t,$$

$$h_{-\infty, \kappa_2} : (-\infty, \kappa_2) \to \mathbb{R}, \quad h_{-\infty, \kappa_2}(t) = t + (\kappa_2 - t)^{-1},$$

$$h_{\kappa_1, +\infty} : (\kappa_1, +\infty) \to \mathbb{R}, \quad h_{\kappa_1, +\infty}(t) = t + (\kappa_1 - t)^{-1}.$$

(1.2) Remark. All of these functions are monotone increasing; hence so are their inverse functions. Also, if $\hat{\kappa} \in L^2[0, 1]$, then $\kappa = h_{\kappa_1, \kappa_2}^{-1} \circ \hat{\kappa} \in L^2[0, 1]$ as well. This is obvious if $(\kappa_1, \kappa_2)$ is bounded, and if one of $\kappa_1, \kappa_2$ is infinite then it is a consequence of the fact that $h_{\kappa_1, \kappa_2}^{-1}(t)$ diverges linearly to $\pm \infty$ with respect to $t$.

In all that follows, $E$ denotes the separable Hilbert space $L^2[0, 1] \times L^2[0, 1]$. The $(i, j)$-entry of a matrix $A$ will be denoted by $A(i, j)$.

(1.3) Definition. Let $-\infty \leq \kappa_1 < \kappa_2 \leq +\infty$ and $P \in UT\mathbb{C}$. A curve $\gamma : [0, 1] \to \mathbb{C}$, $\gamma = \gamma_1 + i\gamma_2$, will be called $(\kappa_1, \kappa_2)$-admissible if $\gamma_1 = \Phi^{(1, 3)}$, $\gamma_2 = \Phi^{(2, 3)}$ for $\Phi : [0, 1] \to UT\mathbb{C}$ satisfying (11), with

(12) $$\sigma = h^{-1} \circ \hat{\sigma}, \quad \kappa = h_{\kappa_1, \kappa_2}^{-1} \circ \hat{\kappa}, \quad (\hat{\sigma}, \hat{\kappa}) \in E.$$ 

When it is not important to keep track of the bounds $\kappa_1, \kappa_2$, we will simply say that $\gamma$ is admissible.

The differential equation (11) has a unique solution $\Phi$ for any $(\hat{\sigma}, \hat{\kappa}) \in E$ and $P \in UT\mathbb{C}$. This follows from [Younes 2010, Theorem C.3] using the fact that $\sigma, \kappa \in L^2[0, 1] \subset L^1[0, 1]$. Moreover, $\Phi$ is absolutely continuous [Younes 2010, p. 385] and defined over all of $[0, 1]$ (since $\mathbb{C}$ is complete). The resulting maps $t : [0, 1] \to \mathbb{S}^1$, $n : [0, 1] \to \mathbb{S}^1$ and $\gamma : [0, 1] \to \mathbb{C}$, obtained from the first, second
and third columns of $\Phi$, respectively, are thus absolutely continuous. It follows from (11) that

\[(13) \quad \dot{\gamma} = \sigma t, \quad \dot{i} = \sigma \kappa n \quad \text{and} \quad \dot{n} = -\sigma \kappa t.\]

Furthermore, if $\Psi$ denotes the $2 \times 2$ matrix obtained from $\Phi$ by discarding its third column and line, then $\Psi : [0, 1] \to SO_2$, as one sees by differentiating $\Psi \Psi^T$, using (11) and noting that $\Psi(0) \in SO_2$. Hence, $n = it$. Differentiation of $|t|^2$ yields that

$$|n(t)| = |t(t)| = |t(0)| = 1 \quad \text{for all} \quad t \in [0,1].$$

Comparing with (13), it is thus natural to define $t_{\gamma} = t$, $n_{\gamma} = n$, $\Phi_{\gamma} = \Phi$, and to call $\sigma$ and $\kappa$ the speed and curvature of $\gamma$, respectively, even though $\sigma, \kappa \in L^2[0,1]$. With this definition, $t_{\gamma}, n_{\gamma}, \Phi_{\gamma}$ and any argument $\theta_{\gamma} = \arg \sigma t_{\gamma}$ are absolutely continuous functions, as remarked above. Although $\dot{\gamma} = \sigma t_{\gamma}$ is defined only almost everywhere on $[0,1]$, if we reparametrize $\gamma$ by arc-length then it becomes a regular curve, since $\gamma' = t_{\gamma}$. Instead of thinking of $\gamma$ as corresponding to a pair of $L^2$ functions, it is more helpful to regard $\gamma$ as a regular curve whose curvature is defined only a.e. In fact, all of the concrete examples of admissible curves considered below are piecewise $C^2$ curves.

(1.4) Definition. Let $-\infty \leq \kappa_1 < \kappa_2 \leq +\infty$. For $P \in UT\mathbb{C}$, define $L^{\kappa_2}_{\kappa_1}(P, \cdot)$ to be the set of all ($\kappa_1, \kappa_2$)-admissible curves $\gamma : [0,1] \to \mathbb{C}$ with $\Phi_{\gamma}(0) = P$. This set is identified with $E$ via the correspondence $\gamma \leftrightarrow (\hat{\sigma}, \hat{\kappa})$, thus furnishing $L^{\kappa_2}_{\kappa_1}(P, \cdot)$ with a trivial Hilbert manifold structure.

The “$\mathcal{L}$” is intended to remind one of $L^2$ functions.

(1.5) Lemma. Let $-\infty \leq \kappa_1 < \kappa_2 \leq +\infty$ and $P \in UT\mathbb{C}$. Then

$$F : L^{\kappa_2}_{\kappa_1}(P, \cdot) \to UT\mathbb{C}, \quad \gamma \mapsto \Phi_{\gamma}(1),$$

is a submersion. Consequently, it is an open map.

Proof. Let $\delta > 0$, $r \in (-\delta, \delta)$ and $\hat{\sigma}(r), \hat{\kappa}(r) \in L^2[0,1]$ be one-parameter families of functions; set $\sigma(r) = h^{-1} \circ \hat{\sigma}(r), \kappa(r) = h^{-1}_{\kappa_1, \kappa_2} \circ \hat{\kappa}(r)$. Define a corresponding family of curves $\Lambda(r) : [0,1] \to \mathfrak{h}$ by

$$\Lambda(r) = \sigma(r) \begin{pmatrix} 0 & -\kappa(r) & 1 \\ \kappa(r) & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Denoting derivatives with respect to $t$ (resp. $r$) by a ‘ (resp. ’), let the map $\Phi(r) : [0,1] \to UT\mathbb{C}, \; t \mapsto \Phi(r)(t)$, be the solution of $\dot{\Phi}(r) = \Phi(r)\Lambda(r)$. A
straightforward computation shows that
\[
\Phi'(r)(t)\left(\Phi(r)(t)\right)^{-1} = \int_0^t \Phi(r)(\tau) \Lambda'(r)(\tau) \left(\Phi(r)(\tau)\right)^{-1} \, d\tau \quad (r \in (-\delta, \delta), \ t \in [0, 1]).
\]
Let \( \Lambda'(0) \) consist of three smooth narrow bumps at times \( t = t_0, t = t_1 \) and \( t = t_2 \), with each \( t_i \in (0, 1) \) close to 1. Let \( \Psi = \Phi(0) \); setting \( r = 0 \) in the previous expression, we deduce that
\[
\Psi(1)^{-1} \Phi'(0)(1) \approx \sum_{i=1}^3 \left(\Psi(t_i)^{-1} \Psi(1)\right)^{-1} \Lambda'(0)(t_i) \left(\Psi(t_i)^{-1} \Psi(1)\right) - 1.
\]
Since each \( \Lambda(r) \) is a curve in the open convex cone
\[
\{aA + bB : a \in \mathbb{R}, b > 0 \text{ and } \kappa_1 b < a < \kappa_2 b\},
\]
we can make \( \Lambda'(0)(t_i) \) assume any value in the vector subspace \( \nu \) generated by \( A \) and \( B \) (with \( A, B \) as in (9)). Another computation using the fact that \( \sigma(0) > 0 \) a.e. shows that the planes \( \nu \) and \( \left(\Psi(t_i)^{-1} \Psi(1)\right)^{-1} \nu \left(\Psi(t_i)^{-1} \Psi(1)\right) \) are transversal for small \( 1 - t_i \), with the angle between them proportional to \( (1 - t_i) + o(1 - t_i) \). Hence, any vector in \( \nu \) can be written in the form \( \Psi(1)^{-1} \Phi'(0)(1) \) for a suitable choice of \( \Lambda'(0) \), which shows that \( F \) is a submersion. \( \square \)

1.6 Definition. Let \(-\infty \leq \kappa_1 < \kappa_2 \leq +\infty\) and \( P, Q \in \mathcal{UTC} \). Define \( \mathcal{L}^{k_2}_{k_1}(P, Q) \) to be the subspace of \( \mathcal{L}^{k_2}_{k_1}(P, \cdot) \) consisting of all \( \gamma \in \mathcal{L}^{k_2}_{k_1}(P, \cdot) \) such that \( \Phi_\gamma(1) = Q \).

It follows from (1.5) that \( \mathcal{L}^{k_2}_{k_1}(P, Q) \) is a closed submanifold of codimension 3 in \( \mathcal{L}^{k_2}_{k_1}(P, \cdot) \equiv E \); the proof that \( \mathcal{L}^{k_2}_{k_1}(P, Q) \) is always nonempty is postponed until Section 4.

The following lemmas contain all the results on infinite-dimensional manifolds that we shall use.

1.7 Lemma. Let \( M, N \) be (infinite-dimensional) separable Banach manifolds. Then:

(a) \( M \) is locally path-connected. In particular, its connected and path components coincide.

(b) If \( F : M \to N \) is a weak homotopy equivalence, then \( F \) is homotopic to a homeomorphism.

(c) Let \( E \) and \( F \) be separable Banach spaces. Suppose \( i : F \to E \) is a bounded, injective linear map with dense image and \( M \subset E \) is a smooth closed submanifold of finite codimension. Then \( N = i^{-1}(M) \) is a smooth closed submanifold of \( F \) and \( i : N \to M \) is a homotopy equivalence.
Proof. Part (a) is obvious. Part (b) follows from [Palais 1966, Theorem 15], [Burghelea and Kuiper 1969, Theorem 9] and [Henderson 1969, Corollary 3]. Part (c) is [Burghelea et al. 2003, Theorem 2].

\[(1.8)\] Lemma. Let \(E\) be a separable Hilbert space, \(D \subset E\) a dense vector subspace, \(L \subset E\) a submanifold of finite codimension and \(U\) an open subset of \(L\). If \(K\) is a finite simplicial complex and \(f : |K| \to U\) a continuous map, then \(f\) is homotopic within \(U\) to a map \(|K| \to D \cap U\).

\[\proof.\] See [Saldanha and Zühlke 2013, Lemma 1.10].

\[(1.9)\] Corollary. Let \(\kappa_1 < \kappa_2\) and \(P, Q \in UT\). Then the subset of all smooth curves in \(L^{\kappa_2}_{k_1}(P, Q)\) is dense in the latter.

\[\proof.\] Take \(E = L^2[0, 1] \times L^2[0, 1], D = C^\infty[0, 1] \times C^\infty[0, 1]\) and \(U\) an open subset of \(L = L^{\kappa_2}_{k_1}(P, Q)\). Then it is a trivial consequence of (1.8) that \(D \cap U \neq \emptyset\) if \(U \neq \emptyset\).

\[(1.10)\] Lemma. Let \((\kappa_1, \kappa_2) \subset (\bar{k}_1, \bar{k}_2)\) and \(P, Q \in UT\). Then

\[
j : C^{\kappa_2}_{k_1}(P, Q) \to L^{\bar{k}_2}_{\bar{k}_1}(P, Q), \quad \gamma \mapsto (\hat{\sigma}, \hat{k}),
\]

where \(\hat{\sigma} = h \circ |\gamma|\) and \(\hat{k} = h_{\bar{k}_1, \bar{k}_2} \circ \kappa_\gamma\), is a continuous injection for all \(r \geq 2\). Furthermore, the actual curve in \(\mathbb{C}\) corresponding to \(j(\gamma) \in L^{\bar{k}_2}_{\bar{k}_1}(P, Q)\) is \(\gamma\) itself.

\[\proof.\] The curve corresponding to the right side of (14) in \(L^{\bar{k}_2}_{\bar{k}_1}(P, \cdot)\) is the solution of (11) with

\[\sigma = h^{-1}_1 \circ \hat{\sigma} = |\gamma| \quad \text{and} \quad \kappa = h^{-1}_{\bar{k}_1, \bar{k}_2} \circ \hat{k} = \kappa_\gamma.\]

By uniqueness, this solution must equal \(\gamma\). In particular, \(j\) is injective and its image is indeed contained in \(L^{\bar{k}_2}_{\bar{k}_1}(P, Q)\). Continuity of \(j\) is clear: if \(\eta\) is \(C^r\)-close to \(\gamma\), then \(\sigma_\eta\) (resp. \(\kappa_\eta\)) is \(C^1\)-close (resp. \(C^0\)-close) to \(\sigma_\gamma\) (resp. \(\kappa_\gamma\)); hence \(j(\eta)\) is close to \(j(\gamma)\) in the \(L^2\)-norm.

\[\[\]

\[(1.11)\] Corollary. Let \(\kappa_1 < \kappa_2, P, Q \in UT\) and \(\mathcal{U} \subset L^{\kappa_2}_{k_1}(P, Q)\) be open. Let \(K\) be a finite simplicial complex and \(f : |K| \to \mathcal{U}\) a continuous map. Then there exists a continuous \(g : |K| \to \mathcal{U}\) such that

(i) \(f \simeq g\) within \(\mathcal{U}\);

(ii) \(g(a)\) is a smooth curve for all \(a \in K\);

(iii) all derivatives of \(g(a)\) with respect to \(t\) depend continuously on \(a \in K\).

In particular, the set inclusion \(j : C^{\kappa_2}_{k_1}(P, Q) \hookrightarrow L^{\kappa_2}_{k_1}(P, Q)\) in (14) induces surjections \(\pi_k(j^{-1}(\mathcal{U})) \to \pi_k(\mathcal{U})\) for all \(k \in \mathbb{N}\).

\[\proof.\] Parts (i), (ii) follow immediately from (1.8) by setting \(E = L^2[0, 1] \times L^2[0, 1],\)

\(D = C^\infty[0, 1] \times C^\infty[0, 1], L = L^{\kappa_2}_{k_1}(P, Q)\) and \(U = \mathcal{U}\). The image of the function \(g = H_2 : |K| \to \mathcal{U}\) constructed in the proof of (1.8) [Saldanha and Zühlke 2013,
Lemma 1.10] is contained in a finite-dimensional vector subspace of $D$, namely, the one generated by all $\tilde{v}_{ij}$, so (iii) also holds. \hfill $\square$

(1.12) Lemma. Let $\kappa_1 < \kappa_2$ and $P, \ Q \in UTC$. Then the inclusion

$$j : \mathcal{C}_{\kappa_1}^{k_2}(P, \ Q)^r \to \mathcal{L}_{\kappa_1}^{k_2}(P, \ Q)$$

is a homotopy equivalence for any $r \in \mathbb{N}$, $r \geq 2$. Consequently, $\mathcal{C}_{\kappa_1}^{k_2}(P, \ Q)^r$ is homeomorphic to $\mathcal{L}_{\kappa_1}^{k_2}(P, \ Q)$ for any $r \in \mathbb{N}$, $r \geq 2$.

Proof. Let $E = L^2[0, 1] \times L^2[0, 1]$, let $F = C^{r-1}[0, 1] \times C^{r-2}[0, 1]$ (where $C^k[0, 1]$ denotes the set of all $C^k$ functions $[0, 1] \to \mathbb{R}$ with the $C^k$ norm) and let $i : F \to E$ be set inclusion. Setting $\mathcal{M} = \mathcal{L}_{\kappa_1}^{k_2}(P, \ Q)$, we conclude from (1.7)(c) that $i : N = i^{-1}(\mathcal{M}) \to \mathcal{M}$ is a homotopy equivalence. We claim that $\mathcal{N}$ is homeomorphic to $\mathcal{C}_{\kappa_1}^{k_2}(P, \ Q)^r$, where the homeomorphism $G$ is obtained by associating a pair $(\hat{\sigma}, \hat{k}) \in \mathcal{N}$ to the curve $\gamma$ obtained by solving (11), with $\sigma$ and $\kappa$ as in (12). The lemma will follow from this and the easily verified commutativity of

$$\mathcal{N} \xrightarrow{G} \mathcal{C}_{\kappa_1}^{k_2}(P, \ Q)^r \xrightarrow{j} \mathcal{L}_{\kappa_1}^{k_2}(P, \ Q)$$

Suppose first that $\gamma \in \mathcal{C}_{\kappa_1}^{k_2}(P, \ Q)^r$. Then $|\dot{\gamma}|$ (resp. $\kappa$) is a function $[0, 1] \to \mathbb{R}$ of class $C^{r-1}$ (resp. $C^{r-2}$). Hence, so are $\hat{\sigma} = h \circ |\dot{\gamma}|$ and $\hat{k} = h_{\kappa_1}^{k_2} \circ \kappa$, since $h$ and $h_{\kappa_1}^{k_2}$ are smooth. Moreover, if $\gamma, \eta \in \mathcal{C}_{\kappa_1}^{k_2}(P, \ Q)^r$ are close in the $C^r$ topology, then $\hat{k}_{\gamma}$ is $C^{r-2}$-close to $\hat{k}_{\eta}$ and $\hat{\sigma}_{\gamma}$ is $C^{r-1}$-close to $\hat{\sigma}_{\eta}$.

Conversely, if $(\hat{\sigma}, \hat{k}) \in \mathcal{N}$, then $\sigma = h^{-1} \circ \hat{\sigma}$ is of class $C^{r-1}$ and $\kappa = (h_{\kappa_1}^{k_2})^{-1} \circ \hat{k}$ is of class $C^{r-2}$. Since all functions on the right side of (11) are of class (at least) $C^{r-2}$, the solution $t = t_{\gamma}$ to this initial value problem is of class $C^{r-1}$. Moreover, $\dot{\gamma} = \sigma t$; hence the velocity vector of $\gamma$ is seen to be of class $C^{r-1}$. We conclude that $\gamma$ is a curve of class $C^r$. Further, continuous dependence on the parameters of a differential equation shows that the correspondence $(\hat{\sigma}, \hat{k}) \mapsto t_{\gamma}$ is continuous. Since $\gamma$ is obtained by integrating $\sigma t_{\gamma}$, we deduce that the map $(\hat{\sigma}, \hat{k}) \mapsto \gamma$ is likewise continuous.

The last assertion of the lemma follows from (1.7)(b). \hfill $\square$

(1.13) Definition. Let $P = (p, w), \ Q = (q, z) \in \mathbb{C} \times \mathbb{S}^1$. Given $\theta_1 \in \mathbb{R}$ satisfying $e^{i\theta_1} = z\bar{w}$, we denote by $\mathcal{L}_{\kappa_1}^{k_2}(P, \ Q; \theta_1)$ the subspace of $\mathcal{L}_{\kappa_1}^{k_2}(P, \ Q)$ consisting of all curves which have total turning equal to $\theta_1$. When $P = (0, 1)$, the space $\mathcal{L}_{\kappa_1}^{k_2}(P, \ Q)$ (resp. $\mathcal{L}_{\kappa_1}^{k_2}(P, \ Q; \theta_1)$) will be denoted simply by $\mathcal{L}_{\kappa_1}^{k_2}(Q)$ (resp. $\mathcal{L}_{\kappa_1}^{k_2}(Q; \theta_1)$).
Notice that \((0, 1) \in \mathbb{C} \times S^1\) corresponds to the identity element in the group structure of \(UT\mathbb{C}\). It will be proved in Section 4 that \(\mathcal{L}^\kappa_{\kappa_1}(P, Q; \theta_1)\) is never empty if \(\kappa_1 \kappa_2 < 0\), but may be empty if \(\kappa_1 \kappa_2 \geq 0\), depending on the value of \(\theta_1\).

The next two results let us reparametrize a family of curves to better suit our needs.

(1.14) Lemma. Let \(\mathcal{M} = \mathcal{L}^\kappa_{\kappa_1}(P, Q)\) or \(\mathcal{M} = \mathcal{C}^\kappa_{\kappa_1}(P, Q)\). Let \(A\) be a topological space and \(A \to \mathcal{M}\), \(a \mapsto \gamma_a\), be a continuous map. Then there exists a homotopy \(\gamma^r_a : [0, 1] \to \mathcal{M}\), \(r \in [0, 1]\), such that for any \(a \in A\),

(i) \(\gamma^0_a = \gamma_a\) and \(\gamma^1_a\) is parametrized so that \(|\dot{\gamma}^1_a(t)|\) is independent of \(t\);

(ii) \(\gamma^r_a\) is an orientation-preserving reparametrization of \(\gamma_a\) for all \(r \in [0, 1]\).

Proof. Let \(s_a(t) = \int_0^t |\dot{\gamma}_a(\tau)| \, d\tau\) be the arc-length parameter of \(\gamma_a\), \(L_a\) its length and \(\tau_a : [0, L_a] \to [0, 1]\) the inverse function of \(s_a\). Define \(\gamma^r_a : [0, 1] \to \mathcal{M}\) by

\[
\gamma^r_a(t) = \gamma_a((1-r)t + r \tau_a(L_a t)) \quad (r, t \in [0, 1], a \in A).
\]

Then \(\gamma^r_a\) is the desired homotopy. \(\square\)

(1.15) Corollary. Let \(\mathcal{M} = \mathcal{L}^\kappa_{\kappa_1}(P, Q)\) or \(\mathcal{M} = \mathcal{C}^\kappa_{\kappa_1}(P, Q)\). Let \(A\) be a topological space and \(f : S^0 \times A \to \mathcal{M}\) a continuous map such that for all \(a \in A\), \(f(1, a)\) is an orientation-preserving reparametrization of \(f(-1, a)\). Then \(f\) admits a continuous extension \(F : A \times [-1, 1] \to \mathcal{M}\) with the property that \(f(r, a)\) is an orientation-preserving reparametrization of \(f(-1, a)\) for all \(r \in [-1, 1], a \in A\). \(\square\)

It is assumed in (1.14) and (1.15) that the parametrizations of all curves have domain \([0, 1]\), but it is clearly possible to have these intervals depend (continuously) on \(a\). A typical application is to reparametrize all curves in a family by arc-length, not just proportionally to arc-length as in (1.14).

Spaces of curves with curvature in a closed interval.

(1.16) Definition. Let \(P, Q \in UT\mathbb{C}\) and \(-\infty < \kappa_1 < \kappa_2 < +\infty\). Define \(\hat{\mathcal{L}}^\kappa_{\kappa_1}(P, Q)\) to be the set of all \(C^1\) regular plane curves \(\gamma : [0, 1] \to \mathbb{C}\) satisfying

(i) \(\Phi_\gamma(0) = P\) and \(\Phi_\gamma(1) = Q\);

(ii) \(\kappa_1 \leq \frac{\theta(s_1) - \theta(s_2)}{s_1 - s_2} \leq \kappa_2\)

for any \(s_1 \neq s_2 \in [0, L]\). (Here the parameter is the arc-length of \(\gamma\), \(L\) is its length and \(\theta : [0, L] \to \mathbb{R}\) is an argument of \(t_\gamma\).)

Condition (ii) implies that \(\theta\) is a Lipschitz function. In particular, it is absolutely continuous, and its derivative \(\kappa_\gamma\) lies in \(L^2\), since it is bounded. We give this set the topology induced by the following distance function \(d\): given \(\gamma, \eta \in \hat{\mathcal{L}}^\kappa_{\kappa_1}(P, Q)\), set

\[
d(\gamma, \eta) = \|\gamma - \eta\|_2 + \|\dot{\gamma} - \dot{\eta}\|_2 + \|\kappa_\gamma - \kappa_\eta\|_2.
\]

For \(P = (0, 1) \in \mathbb{C} \times S^1\), we will denote \(\hat{\mathcal{L}}^\kappa_{\kappa_1}(P, Q)\) simply by \(\hat{\mathcal{L}}^\kappa_{\kappa_1}(Q)\).
**Remark.** This definition is essentially due to L. E. Dubins, who studied paths of minimal length, now called *Dubins paths*, in \( \hat{L}_{\kappa_0}^{+}(P, Q) \) (\( \kappa_0 > 0 \)). Such shortest paths always exist, but may not be unique in some special cases (see Proposition 1 and the corollary to Theorem I of [Dubins 1957]). His main result states that any Dubins path is the concatenation of at most three pieces, each of which is either a line segment or an arc of circle of radius \( 1/\kappa_0 \) (see [loc. cit., Theorem I] for the precise statement). Dubins paths and variations thereof have many applications in engineering and are the subject of a vast literature. The space \( \hat{L}_{\kappa_0}^{\kappa_1}(P, Q) \) will play a minor role in our investigations. Its topology has been chosen to ensure that the following result holds.

**(1.17) Lemma.** Let \((\kappa_1, \kappa_2) \subset [\bar{\kappa}_1, \bar{\kappa}_2] \subset (\bar{\kappa}_1, \bar{\kappa}_2)\) and \(P, Q \in UTC\). Then the set inclusions

\[
\mathcal{C}_{\kappa_1}^{\kappa_2}(P, Q) \to \hat{L}_{\kappa_1}^{\kappa_2}(P, Q) \quad \text{and} \quad \hat{L}_{\kappa_1}^{\kappa_2}(P, Q) \to \mathcal{L}_{\kappa_1}^{\kappa_2}(P, Q)
\]

are continuous injections.

**Proof.** The proof is a straightforward verification, which will be left to the reader. □

### 2. Normal translation

The *radius of curvature* \( \rho \) of an admissible curve \( \gamma \) is given by \( \rho = 1/\kappa \); when \( \kappa(t) = 0 \), it is to be understood that \( \rho(t) = \infty \) (unsigned infinity). An analogue of the following construction has already appeared in [Saldanha and Zühlke 2013]. It can be used to uniformly shift the radii of curvature of a family of curves.

**(2.1) Definition.** Let \( \gamma : [0, 1] \to \mathbb{C} \) be admissible and \( u \in \mathbb{R} \). The *normal translation* \( \gamma_u \) of \( \gamma \) by \( u \) is the curve given by

\[
\gamma_u(t) = \gamma(t) + un(t) \quad (t \in [0, 1]).
\]

Observe that the normal translation \( \alpha_u \) of a circle \( \alpha \) of radius of curvature \( \rho \in \mathbb{R} \setminus \{0\} \) is a circle of radius of curvature \( \rho - u \) for any \( u \) in the component of \( \mathbb{R} \setminus \{\rho\} \) containing 0 (see Figure 2). The following lemma generalizes this to arbitrary curves.

**(2.2) Lemma.** Let \( \gamma \in \mathcal{L}_{\kappa_1}^{\kappa_2}(P, Q) \) be parametrized proportionally to arc-length and let \( t, \kappa, \rho \) denote its unit tangent, curvature and radius of curvature, respectively. Suppose \( u \in \mathbb{R} \) satisfies \( 1 - uk > 0 \) for all \( k \in (\kappa_1, \kappa_2) \) and set

\[
(15) \quad \tilde{\kappa}_i = \frac{\kappa_i}{1 - uk_i} \quad (i = 1, 2).
\]

Then the normal translation \( \gamma_u \) of \( \gamma \) by \( u \) has the following properties:
Figure 2. The normal translation of a general curve $\gamma$ and of a circle $\alpha$.

(a) $\gamma_u \in \mathcal{L}_{\bar{\kappa}_i}(\bar{P}, \bar{Q})$ for $\bar{P} = (p + iu, w)$, $\bar{Q} = (q + iuz, z)$ and its unit tangent $\bar{t}$ satisfies $\bar{t}(t) = t(t)$ for each $t \in [0, 1]$. In particular, $\gamma$ and $\gamma_u$ have the same total turning.

(b) $(\gamma_u)_u = \gamma$.

(c) If $\eta$ is a reparametrization of $\gamma$, then $\eta_u$ is a reparametrization of $\gamma_u$.

(d) For almost every $t \in [0, 1]$, the curvature $\bar{\kappa}$ of $\gamma_u$ is given by

$$\bar{\kappa}(t) = \frac{\kappa(t)}{1 - u\kappa(t)}$$

and its radius of curvature $\bar{\rho}$ by

$$\bar{\rho}(t) = \rho(t) - u.$$
\( \mathbf{\check{n}} = \mathbf{n} \). That \( \Phi_{\gamma_u}(0) = \mathbf{\check{P}} \) and \( \Phi_{\gamma_u}(1) = \mathbf{\check{Q}} \) then follows immediately from the definition. This establishes (a) except for the fact that \( \gamma_u \) is \((\check{\kappa}, \check{\kappa})\)-admissible, which will be proved below.

Part (b) is an easy verification:

\[
(\gamma_u)_{-u} = \gamma_u - u \mathbf{\check{n}} = (\gamma + u \mathbf{n}) - u \mathbf{n} = \gamma.
\]

Part (c) is obvious.

We know that the curvature \( \check{\kappa} \) of \( \gamma_u \) is given by the quotient of \( \Lambda^{(2,1)} \) by \( \Lambda^{(1,3)} \), that is,

\[
\check{\kappa} = \frac{\kappa}{1 - u \kappa} = \frac{1}{\rho - u} = \frac{1}{\check{\rho}}.
\]

This proves (d).

It is straightforward to check that \( u \in \mathbb{R} \) satisfies \( 1 - u \kappa > 0 \) for all \( \kappa \in (\kappa_1, \kappa_2) \) if and only if \( u \) lies in the maximal closed interval \( J \) containing \( 0 \) and not containing any number of the form \( 1/k \) for \( k \in (\kappa_1, \kappa_2) \). More explicitly:

(i) If \( 0 \leq \kappa_1 < \kappa_2 \) then \( J = (-\infty, \rho_2] \);
(ii) If \( \kappa_1 < 0 < \kappa_2 \) then \( J = [\rho_1, \rho_2] \);
(iii) If \( \kappa_1 < \kappa_2 \leq 0 \) then \( J = [\rho_1, +\infty) \).

By (17), \( |\dot{\gamma}_u| = L(1 - u \kappa) \). To establish that \( \gamma_u \) is \((\check{\kappa}, \check{\kappa})\)-admissible, it suffices to prove that

\[
(18) \quad h_{0,+\infty} \circ (1 - u \kappa) = (1 - u \kappa) - (1 - u \kappa)^{-1} \in L^2[0, 1],
\]

\[
(19) \quad h_{\check{\kappa}_1, \check{\kappa}_2} \circ \check{\kappa} \in L^2[0, 1].
\]

By (1.2), \( \kappa \in L^2[0, 1] \); hence so is \((1 - u \kappa)\). Moreover, \((1 - u \kappa)^{-1}\) is bounded unless \( u \) is one of the endpoints of \( J \), but we claim that even in this case \( (1 - u \kappa)^{-1} \in L^2[0, 1] \). Suppose for concreteness that \( u = \rho_2 \in \partial J \). If \( \kappa_2 = +\infty \) (\( \rho_2 = 0 \)) then there is nothing to prove, and otherwise

\[
(20) \quad (1 - u \kappa)^{-1} = (1 - \rho_2 \kappa)^{-1} = \kappa_2(\kappa_2 - \kappa)^{-1}.
\]

Now by hypothesis, \( \gamma \in \mathcal{L}_{\kappa_1}^{2}(P, Q) \); therefore

\[
(21) \quad h_{\check{\kappa}_1, \check{\kappa}_2} \circ \kappa = (\kappa_1 - \kappa)^{-1} + (\kappa_2 - \kappa)^{-1} \in L^2[0, 1].
\]

This implies that both

\[
(\kappa_1 - \kappa)^{-1} \in L^2[0, 1] \quad \text{and} \quad (\kappa_2 - \kappa)^{-1} \in L^2[0, 1],
\]

since as one of them increases in absolute value, the other one decreases. Consequently, (20) lies in \( L^2[0, 1] \) and (18) follows from Minkowski’s inequality.

The proof of (19) involves the tedious consideration of several cases, because it depends on which of the four \( h \) functions defined on p. 193 is used, both for \((\kappa_1, \kappa_2)\)
As above, it follows that each of the summands lies in $L^\kappa$. Because $\kappa \in (\kappa_1, \kappa_2)$ is bounded, this is a sum of two functions in $L^2(0, 1)$ by (21); hence it lies in $L^2(0, 1)$. If $u$ is an endpoint $\rho_i$ of $J$ then $\tilde{\kappa}_i$ is infinite. For instance, if $u = \rho_2$ then

$$h_{\tilde{\kappa}_1, \tilde{\kappa}_2} \circ \tilde{\kappa} = (1 - u\kappa)(1 - u\kappa_1)(\kappa_1 - \kappa)^{-1} + (1 - u\kappa)(1 - u\kappa_2)(\kappa_2 - \kappa)^{-1}.$$

Because $\kappa$ is bounded, we conclude from (21) that (19) holds in this case also.

If one of the $\kappa_i$, say $\kappa_2$, is infinite, then the hypothesis that $\gamma$ is admissible implies that

$$h_{\kappa_1, +\infty} \circ \kappa = (\kappa_1 - \kappa)^{-1} + \kappa \in L^2(0, 1).$$

As above, it follows that each of the summands lies in $L^2(0, 1)$. If $u \neq \rho_1$ then $\tilde{\kappa}_1 = \kappa_1(1 - u\kappa_1), \tilde{\kappa}_2 = -1/u$ are both finite, and

$$h_{\tilde{\kappa}_1, \tilde{\kappa}_2} \circ \tilde{\kappa} = (1 - u\kappa_1)(1 - u\kappa)(\kappa_1 - \kappa)^{-1} - u(1 - u\kappa).$$

Observe that $(1 - u\kappa)(\kappa_1 - \kappa)^{-1} \in L^2(0, 1)$ because as $\kappa$ increases to $+\infty$, $(\kappa_1 - \kappa)^{-1}$ remains bounded, while as $\kappa \to \kappa_1$, obviously $(1 - u\kappa)$ remains bounded. Thus, (19) holds. We leave the similar verification in the remaining cases to the reader. □

(2.3) Remark. The necessity of reparametrizing an admissible curve by arc-length before applying normal translation stems from the fact that the product of two $L^2$ functions need not be of class $L^2$: for a general parametrization, the speed of $\gamma_u$ is given by $\sigma(1 - u\kappa)$, where $\sigma, \kappa$ are the speed and curvature of $\gamma$; hence, $\gamma_u$ need not be admissible. This has no serious consequences because of (1.14).

The next result greatly simplifies the study of the spaces $L^\kappa_{\kappa_1}(P, Q)$. In all that follows, the notation $X \approx Y$ means that $X$ is homeomorphic to $Y$.

(2.4) Theorem. Let $P = (p, w), Q = (q, z) \in \mathbb{C} \times \mathbb{S}^1, -\infty \leq \kappa_1 < \kappa_2 \leq +\infty$ and $\rho_i = 1/\kappa_i$.

(a) Suppose $\kappa_1 < 0 < \kappa_2$. If at least one of $\kappa_1, \kappa_2$ is finite, then $L^\kappa_{\kappa_1}(P, Q) \approx L^{+1}(Q_1)$ for

$$Q_1 = \left(\frac{2}{\rho_2 - \rho_1} - \bar{w}((q - p) + (\frac{i}{2}(\rho_1 + \rho_2)(z - w)) z \bar{w}\right).$$

(b) Suppose $0 < \kappa_1 < \kappa_2$. Then $L^\kappa_{\kappa_1}(P, Q) \approx L^{+\infty}(Q_2)$ for

$$Q_2 = \left(\frac{\bar{w}}{\rho_1 - \rho_2}((q - p) + i\rho_2(z - w)) z \bar{w}\right).$$
In cases (a)–(c) (resp. (d)–(e)), the total turning of the image of a curve under the homeomorphism is equal (resp. opposite) to that of the original curve.

Proof. Suppose first that $\kappa_1 < 0 < \kappa_2$ and let $k \in (\kappa_1, \kappa_2)$ be arbitrary. If $\rho_1 + \rho_2 \leq 0$, then

$$1 - \left(\frac{\rho_1 + \rho_2}{2}\right)k > 1 - \left(\frac{\rho_1 + \rho_2}{2}\right)\kappa_1 = \frac{1}{2}(1 - \rho_2\kappa_1) \geq \frac{1}{2} > 0,$$

and if $\rho_1 + \rho_2 \geq 0$, then

$$1 - \left(\frac{\rho_1 + \rho_2}{2}\right)k > 1 - \left(\frac{\rho_1 + \rho_2}{2}\right)\kappa_2 = \frac{1}{2}(1 - \rho_1\kappa_2) \geq \frac{1}{2} > 0.$$ 

Consequently, $u = (\rho_1 + \rho_2)/2$ satisfies the hypothesis of (2.2). Let

$$\kappa_0 = \frac{2}{\rho_2 - \rho_1}.$$ 

Note that $0 < \kappa_0 < +\infty$; in the notation of (2.2), $-\kappa_0 = \bar{\kappa}_1$ and $\kappa_0 = \bar{\kappa}_2$. Define a map $F : \mathcal{L}_{-k_1}^{k_2}(P, Q) \to \mathcal{L}_{-k_0}^{+k_0}(-\bar{P}, \bar{Q})$ by letting $F(\gamma)$ be the translation by $u$ of its reparametrization (still with domain $[0, 1]$) by a multiple of arc-length. This is continuous by (1.14). In fact, it is a homotopy equivalence: there is a similarly defined map $G : \mathcal{L}_{-k_0}^{+k_0}(-\bar{P}, \bar{Q}) \to \mathcal{L}_{k_1}^{k_2}(P, Q)$ using translation by $-u$, and $GF(\gamma)$ is just a reparametrization of $\gamma$ by (2.2)(b) and (c).

Let $T : \mathbb{C} \to \mathbb{C}$ be the dilatation $x \mapsto \kappa_0 x$. If $\gamma \in \mathcal{L}_{-k_0}^{+k_0}(-\bar{P}, \bar{Q})$, then $T \circ \gamma$ lies in $\mathcal{L}_{-1}^{+1}(-\bar{P}, \bar{Q})$, where

$$\tilde{P} = \left(\kappa_0 \left( p + \frac{\rho_1 + \rho_2}{2} i w \right), w \right), \quad \tilde{Q} = \left( \kappa_0 \left( q + \frac{\rho_1 + \rho_2}{2} i z \right), z \right),$$

and the correspondence $\gamma \mapsto T \circ \gamma$ yields a homeomorphism between these two spaces. Write $\tilde{P} = (\tilde{p}, w) \in \mathbb{C} \times \mathbb{S}^1$ and let $E : \mathbb{C} \to \mathbb{C}$ be the Euclidean motion given by $E(x) = \tilde{w}(x - \tilde{p})$. Then the map $\gamma \mapsto E \circ \gamma$ is a homeomorphism from $\mathcal{L}_{-1}^{+1}(-\bar{P}, \bar{Q})$ onto $\mathcal{L}_{-1}^{+1}(Q_1)$, with $Q_1$ as in the statement. The composition of all of these maps yields a homotopy equivalence $\mathcal{L}_{k_1}^{k_2}(P, Q) \to \mathcal{L}_{-1}^{+1}(Q_1)$, which is homotopic to a homeomorphism by (1.7)(b).
The proofs of parts (b) and (c) are analogous, so only a brief outline will be provided. In part (b), we first use normal translation by $\rho_2$, and then compose with the dilatation $x \mapsto x/(\rho_1 - \rho_2)$ and an Euclidean motion; in part (c) the dilatation is not necessary. Parts (d) and (e) follow from (b) and (c), respectively, by reversing the orientation of all curves in the corresponding space.

By (2.2)(a), the normal translations used in establishing (a)–(c) preserve the total turning of a curve. Clearly, so do dilatations and Euclidean motions, while a reversal of orientation changes the sign of the total turning. This proves the last assertion of the theorem. □

(2.5) Remark. Normal translations, and hence also the homotopy equivalences constructed in (2.4), do not generally respect inequalities between lengths. This is clear from Figure 2: two circles of the same radius $r > 0$ but different orientations are mapped to circles of radii equal to $r \pm u$ under normal translation by $u \in (0, r)$. See also the remarks at the end of Section 9.

A more concise version of (2.4) is the following; recall that $0(\pm \infty) = 0$ by convention.

(2.6) Corollary. Let $P$, $Q \in UT\subset$. Then $L_{\kappa_2}^{\kappa_1}(P, Q)$ is homeomorphic to a space of type $L_{-1}^{+1}(Q_0)$, $L_0^{+\infty}(Q_0)$ or $L_1^{+\infty}(Q_0)$, according to whether $\kappa_1\kappa_2 < 0$, $\kappa_1\kappa_2 = 0$ or $\kappa_1\kappa_2 > 0$, respectively. □

Out of the three possibilities, the spaces of type $L_{\kappa_1}^{\kappa_2}(P, Q)$ with $\kappa_1\kappa_2 < 0$ are the ones with the most interesting topological properties. We deal with the two remaining cases in Section 7.

(2.7) Remark. We may replace $L$ with $C$ throughout in the statement of (2.4). In fact, the difficulty indicated in (2.3) disappears in this case, so the proof is simpler because it is not necessary to reparametrize the curves by arc-length before applying normal translation. This yields explicit homeomorphisms of the corresponding spaces, without relying on (1.7)(b). Because the curves in a space of type $\hat{L}_{\kappa_1}^{\kappa_2}$ are $C^1$ regular by definition, this simpler proof also works for this class (except that here $\kappa_1 < \kappa_2$ must be finite); see (9.1) for the precise statement.

3. Topology of $U_c$

(3.1) Definition. Let $\gamma : [0, 1] \to \subset$ be a regular curve and $\theta : [0, 1] \to \mathbb{R}$ be an argument of $t_\gamma$. The amplitude of $\gamma$ is given by

$$\omega = \sup_{t \in [0,1]} \theta(t) - \inf_{t \in [0,1]} \theta(t).$$

We call $\gamma$ condensed, critical or diffuse according to whether $\omega < \pi$, $\omega = \pi$ or $\omega > \pi$. 
Our main objective now is to understand the topology of $\mathcal{L}_{-\kappa_0}^{+\kappa_0}(P, Q)$ when $\kappa_1\kappa_2 < 0$. By (2.6), no generality is lost in assuming that $\kappa_1 = -1, \kappa_2 = +1$ and $P = (0, 1) \in \mathbb{C} \times S^1$

(3.2) Definition. Let $Q = (q, z) \in \mathbb{C} \times S^1$ and $\theta_1 \in \mathbb{R}$ satisfy $e^{i\theta_1} = z$. We denote by $\mathcal{U}_c, \mathcal{U}_d$ and $\mathcal{T}$ the subspaces of $\mathcal{L}_{-\kappa_0}^{+\kappa_0}(Q; \theta_1)$ consisting of all condensed, diffuse and critical curves, respectively.

(3.3) Theorem. The subspace $\mathcal{U}_c \subset \mathcal{L}_{-\kappa_0}^{+\kappa_0}(Q; \theta_1)$ consisting of all condensed curves is either empty or homeomorphic to $E$, and hence contractible.

Recall that $E$ denotes the separable Hilbert space. In what follows, a function $\phi$ of a real variable will be called increasing (resp. decreasing) if $x < y$ (resp. $x > y$) implies that $\phi(x) \leq \phi(y)$. The previous theorem will be derived as a corollary of the following result.

(3.4) Proposition. Let $\kappa_0 > 0$ and $\hat{\mathcal{U}}_c \subset \hat{\mathcal{L}}_{-\kappa_0}^{+\kappa_0}(Q; \theta_1)$ be the subspace consisting of all condensed curves. If $\hat{\mathcal{U}}_c \neq \emptyset$, then there exists a continuous $H : [0, 1] \times \hat{\mathcal{U}}_c \to \hat{\mathcal{U}}_c$ such that for all $\gamma \in \hat{\mathcal{U}}_c$,

(i) $H(1, \gamma) = \gamma$ and $H(0, \gamma) = \gamma_0$ (where $\gamma_0$ is independent of $\gamma$);
(ii) the amplitude of $\gamma_s = H(s, \gamma)$ is an increasing function of $s \in [0, 1]$;
(iii) the length of $\gamma_s = H(s, \gamma)$ is an increasing function of $s \in [0, 1]$.

In particular, $\hat{\mathcal{U}}_c$ is contractible. Moreover, $\gamma_0$ is the unique curve of minimal length in $\hat{\mathcal{L}}_{-\kappa_0}^{+\kappa_0}(Q)$.

We believe that this proposition and its proof may be useful for other purposes which are not pursued here, e.g., for calculating the minimal length of curves in $\hat{\mathcal{L}}_{-\kappa_0}^{+\kappa_0}(Q)$. We shall first describe the effect of $H$ on a single curve $\gamma \in \hat{\mathcal{U}}_c$ and then derive its main properties separately as lemmas. First we record two results which will be used to show that $H(0, \gamma)$ is independent of $\gamma$.

(3.5) Lemma. Let $Q = (q, z) \in \mathbb{C} \times S^1$, $\gamma \in \hat{\mathcal{L}}_{-\kappa_0}^{+\kappa_0}(Q)$ and $L$ be the length of $\gamma$. Suppose that $q$ lies on the line through $i/\kappa_0$ having direction $-i e^{i\alpha}$ for some $\alpha \in [0, \pi)$. Then $L \geq \alpha/\kappa_0$ and equality holds if and only if $\gamma$ is a reparametrization of the arc of the circle centered at $i/\kappa_0$ joining $0$ to $1/\kappa_0(i - i e^{i\alpha})$.

Proof. We lose no generality in assuming that $\kappa_0 = 1$. If $\alpha = 0$, there is nothing to prove, so suppose $\alpha \in (0, \pi)$. Let $\gamma : [0, L] \to \mathbb{C}$ be parametrized by arc-length, and let $\eta : [0, \alpha] \to \mathbb{C}$ be given by

$$\eta(s) = \int_0^s e^{i\sigma} d\sigma = i - ie^{is} \quad (s \in [0, \alpha]),$$

where $\sigma$ is the arc-length of $\gamma$.
so that $\eta$ is the parametrization by arc-length of the arc of circle described in (3.5); see Figure 3(a). Set

\[ f : [0, \ L] \rightarrow \mathbb{R}, \quad f(s) = \langle \gamma(s) - i, e^{i\alpha} \rangle, \]

\[ g : [0, \ \alpha] \rightarrow \mathbb{R}, \quad g(s) = \langle \eta(s) - i, e^{i\alpha} \rangle. \]

Let $A$ denote the line in the statement. Note that $f(0) = 0$ if and only if $\gamma(s) \in A$. We need to prove that $f(s) < 0$ for all $s \in [0, \alpha) \cap [0, L]$. Let $\theta_\gamma$ be the argument of $t_\gamma$ satisfying $\theta_\gamma(0) = 0$. Then

\[ f'(s) = (e^{i\theta_\gamma(s)}, e^{i\alpha}) = \cos(\alpha - \theta_\gamma(s)) \quad \text{and} \quad g'(s) = (e^{is}, e^{i\alpha}) = \cos(\alpha - s). \]

We have $f(0) = g(0)$. Since $g(s) < 0$ for all $s \in [0, \alpha)$, it suffices to establish that $f'(s) \leq g'(s)$ for all $s \in [0, \alpha] \cap [0, L]$. By the definition of $\hat{\mathcal{L}}^{+1}_{-k_0}(Q)$, $\theta_\gamma$ is 1-Lipschitz. Hence, $|\theta_\gamma(s)| \leq s$ for all $s \in [0, L]$. Consequently,

\[ \alpha - s \leq \alpha - \theta_\gamma(s) \leq \alpha + s \quad \text{for all} \quad s \in [0, L]. \]

In particular, $\alpha - \theta_\gamma(s) \in [0, 2\pi]$ for all $s \in [0, \alpha] \cap [0, L]$. Since the cosine is decreasing over $[0, \pi]$, it follows immediately from (22) that if $\alpha - \theta_\gamma(s) \leq \pi$, then $f'(s) \leq g'(s)$. On the other hand, if $\alpha - \theta_\gamma(s) \in [\pi, 2\pi]$, then from $\alpha - \theta_\gamma(s) \leq \alpha + s$, we obtain that

\[ \cos(\alpha - \theta_\gamma(s)) \leq \cos(\alpha + s) \leq \cos(\alpha - s), \]

the latter inequality coming from $\alpha \in (0, \pi)$ and $s \in [0, \alpha]$. Thus, $f'(s) \leq g'(s)$ in this case also. We conclude that $f(s) \leq g(s) < 0$ for all $s \in [0, \alpha) \cap [0, L]$. In particular, $L \geq \alpha$, as $\gamma(L) \in A$.

If $f(\alpha) = g(\alpha) = 0$, then we must have $f' = g'$, that is, $\theta_\gamma(s) = s$ for all $s \in [0, \alpha]$. Thus, in this case, $\gamma|_{[0,\alpha]}$ is a reparametrization of $\eta|_{[0,\alpha]}$.

(3.6) Corollary. Suppose that $\eta \in \hat{\mathcal{L}}^{+\kappa_0}_{-\kappa_0}(Q)$ is a concatenation of an arc of circle of curvature $\pm \kappa_0$, a line segment, and another arc of circle of curvature $\pm \kappa_0$, where some of these may be degenerate and both arcs have length less than $\pi/\kappa_0$. Then $\eta$ is the unique curve in $\hat{\mathcal{L}}^{+\kappa_0}_{-\kappa_0}(Q)$ of minimal length.
This result should be compared to [Dubins 1957, Proposition 9]. Their proofs are essentially the same.

**Proof.** Let \( \eta : [0, L] \to \mathbb{C} \) be parametrized by arc-length, with \( \eta|[0,L_1], \eta|[L_1,L_2], \) and \( \eta|[L_2,L] \) corresponding to the first arc, line segment and second arc, respectively (see Figure 3(b)). Let \( A_i \) be the line perpendicular to \( \eta'(L_i) \) passing through \( \eta(L_i), i = 1, 2. \) Notice that \( A_1 \) and \( A_2 \) are parallel (or equal). Suppose that \( \gamma : [0, M] \to \mathbb{C} \) is another curve in \( \hat{\mathcal{L}}^{-k_0}(Q) \), parametrated by arc-length. Let

\[
M_1 = \inf\{s \in [0, M] : \gamma(s) \in A_1\}, \quad M_2 = \sup\{s \in [0, M] : \gamma(s) \in A_2\}.
\]

By (3.5), we have \( M_1 \geq L_1 \) and \( M - M_2 \geq L - L_2 \). It is clear that \( M_2 - M_1 \geq L_2 - L_1 \) since any path joining a point of \( A_1 \) to a point of \( A_2 \) must have length greater than or equal to the distance between these lines. Hence, \( M \geq L. \) Furthermore, if equality holds, then \( M_1 = L_1 \), \( M - M_2 = L - L_2 \) and \( M_2 - M_1 = L_2 - L_1. \) By (3.5), the two former equalities imply that \( \gamma|[0,M_1] = \eta|[0,L_1] \) and \( \gamma|[M_2,M] = \eta|[L_2,L]. \) The condition \( M_2 - M_1 = L_2 - L_1 \) then implies that \( \gamma|[M_1,M_2] \) must coincide with the line segment \( \eta|[L_1,L_2]. \) \( \square \)

(3.7) **Remark.** Notice that a condensed curve must be an embedding of \([0, 1]\). In fact, its image is the graph of a function of \( x \), after a suitable choice of the \( x \)-axis.

(3.8) **Construction.** Let \( \gamma \in \hat{\mathcal{U}}_c, \theta : [0, 1] \to \mathbb{R} \) be the argument of \( t_\gamma \) satisfying \( \theta(0) = 0. \) A number \( \varphi \in (-\pi/2, \pi/2) \) will be called an axis of \( \gamma \) if \( (t_\gamma, e^{i\varphi}) > 0 \) for all \( t \in [0, 1] \). Since \( \gamma \) is condensed, the set of all axes of \( \gamma \) is an open interval. The most natural axis, and the center of this interval, is

\[
\bar{\varphi}_\gamma = \frac{1}{2} \left( \sup_{t \in [0,1]} \theta(t) + \inf_{t \in [0,1]} \theta(t) \right).
\]

Let \( \varphi \) be any axis of \( \gamma \). Rotating around the origin through \( \varphi \) and writing \( \gamma(t) = (x(t), y(t)) \) in terms of the new \( x \)- and \( y \)-axes, the hypothesis that \( (t_\gamma, e^{i\varphi}) > 0 \) becomes equivalent to the fact that \( \dot{x} \) is bounded and positive over \([0, 1]\). Let

\[
\gamma(x) = (x, y(x)) \quad (x \in [0, b])
\]

be the reparametrization of \( \gamma \) by \( x \) and define

\[
f : [0, b] \to \mathbb{R} \quad \text{by} \quad f(x) = \dot{y}(x).
\]

Let \( f_s : [0, b] \to \mathbb{R} \) be a family of absolutely continuous functions and set

\[
\gamma_s(x) = \left( x, \int_0^x f_s(u) \, du \right) \quad (x \in [0, b]).
\]

A straightforward computation shows that the curvature of \( \gamma_s \) is given by

\[
\kappa_{\gamma_s}(x) = \frac{\dot{f}_s(x)}{\left(1 + f_s(x)^2\right)^{3/2}} \quad (x \in [0, b]).
\]
Therefore, $\gamma_s$ lies in $\mathcal{L}_{-\kappa_0}^{+\kappa_0}(Q; \theta_1)$ if and only if $f_s$ satisfies

(i) $|\dot{f}_s(x)| \leq \kappa_0 (1 + f_s(x)^2)^{3/2}$ for almost every $x \in [0, b]$ (i.e., $\kappa_{\gamma_s} \in [-\kappa_0, +\kappa_0]$ a.e.);

(ii) $f_s(0) = r_0 := \dot{y}(0)$ and $f_s(b) = r_b := \dot{y}(b)$ (i.e., $t_{\gamma_s}(0) = t_Y(0)$ and $t_{\gamma_s}(b) = t_Y(b)$);

(iii) $\int_0^b f_s(x) \, dx = A_1 := y(b) - y(0)$ (i.e., $\gamma_s(b) = \gamma(b)$).

We will now produce a homotopy of $f = f_1$ through absolutely continuous functions satisfying (i)–(iii).

Define

(24) $\alpha_\pm = \mp \frac{r_0}{\sqrt{1 + r_0^2}}$, \quad $g_\pm(x) = \pm \frac{\kappa_0 x - \alpha_\pm}{\sqrt{1 - (\kappa_0 x - \alpha_\pm)^2}}$ \quad for \quad $x \in \left(\frac{\alpha_\pm - 1}{\kappa_0}, \frac{\alpha_\pm + 1}{\kappa_0}\right)$

(see Figure 4) and, similarly,

(25) $\beta_\pm = \kappa_0 b \pm \frac{r_b}{\sqrt{1 + r_b^2}}$, \quad $h_\pm(x) = \mp \frac{\kappa_0 x - \beta_\pm}{\sqrt{1 - (\kappa_0 x - \beta_\pm)^2}}$ \quad for \quad $x \in \left(\frac{\beta_\pm - 1}{\kappa_0}, \frac{\beta_\pm + 1}{\kappa_0}\right)$.

The functions $g_\pm$ are the solutions of the differential equations $\dot{g} = \pm \kappa_0 (1 + g^2)^{3/2}$ with $g(0) = r_0$. Similarly, $h_\pm$ are the solutions of the differential equations $\dot{h} = \mp \kappa_0 (1 + h^2)^{3/2}$ with $h(b) = r_b$. Extend their domains to all of $\mathbb{R}$ by setting

$g_\pm(x) = \pm \infty$ if $x \geq \frac{\alpha_\pm + 1}{\kappa_0}$ and $g_\pm(x) = \mp \infty$ if $x \leq \frac{\alpha_\pm - 1}{\kappa_0}$.
and do similarly for \( h_{\pm} \). Since the curvature of \( \gamma = \gamma_1 \) takes values in \([-\kappa_0, +\kappa_0]\), condition (i) applied to \( f = f_1 \) gives

\[
(26) \quad g_-(x), h_-(x) \leq f(x) \leq g_+(x), h_+(x) \quad \text{for all } x \in [0, b].
\]

Let

\[
m_- = \inf_{x \in [0, b]} f(x), \quad m_+ = \sup_{x \in [0, b]} f(x),
\]

(27)

\[
\Delta = \{(\mu_-, \mu_+) \in [m_-, m_+] : \mu_- \leq \mu_+\}.
\]

For \((\mu_-, \mu_+) \in \Delta\), let \( f^{(\mu_-, \mu_+)} : [0, b] \to \mathbb{R} \) be given by

\[
(28) \quad f^{(\mu_-, \mu_+)}(x) = \text{median}(h_-(x), g_-(x), \mu_-, f(x), \mu_+, g_+(x), h_+(x))
\]

(see Figure 4). The functions \( f^{(\mu_-, \mu_+)} \) automatically satisfy conditions (i) and (ii).

Define \( A : \Delta \to \mathbb{R} \) to be the area under the graph of \( f^{(\mu_-, \mu_+)} \):

\[
A(\mu_-, \mu_+) = \int_0^b f^{(\mu_-, \mu_+)}(x) \, dx.
\]

It is immediate from (28) that

(A) \( A \) is increasing as a function of either \( \mu_- \) or \( \mu_+ \);

(B) \( A \) is a Lipschitz function of \((\mu_-, \mu_+)\). In fact,

\[
|A(\mu_- + u, \mu_+ + v) - A(\mu_-, \mu_+)| \leq b(|u| + |v|).
\]

By (A), for each \( s \in [0, 1] \), the set

\[
\{(\mu_-, \mu_+) \in \Delta : A(\mu_-, \mu_+) = A_1 \text{ and } \mu_+ - \mu_- = (m_+ - m_-)s\}
\]

is an interval of the latter line in the \((\mu_-, \mu_+)-\text{plane}\). Let \((\mu_-(s), \mu_+(s))\) be the coordinates of the center of this interval. By (B), \( \mu_-(s) \) and \( \mu_+(s) \) are continuous (even Lipschitz), and (A) implies that \( \mu_- \) is a decreasing, while \( \mu_+ \) is an increasing function of \( s \in [0, 1] \). The functions

\[
f_s : [0, b] \to \mathbb{R}, \quad f_s = f^{(\mu_-(s), \mu_+(s))},
\]

satisfy all of conditions (i)–(iii) by construction. We repeat their definition for convenience:

\[
f_s(x) = \text{median}(h_-(x), g_-(x), \mu_-(s), f(x), \mu_+(s), g_+(x), h_+(x)),
\]

(29)

\[
\gamma_s(x) = \left( x, \int_0^x f_s(u) \, du \right) \quad (x \in [0, b]).
\]

We will denote \( \mu_+(0) = \mu_-(0) \) by \( \mu_0 \). The monotonicity of \( \mu_-, \mu_+ \) implies that

\[
(30) \quad \mu_-(s) \leq \mu_0 \leq \mu_+(s) \quad \text{for all } s \in [0, 1]. \quad \square
\]
(3.9) **Remark.** We deduce from (26) and (29) that

$$f_0 = \text{median}(h_-, g_-, \mu_0, g_+, h_+).$$

The graph of $f_0$ is composed of at most three parts: a piece of the graph of $g_-$ or $g_+$, a piece of the graph of the constant function $y = \mu_0$, and a piece of the graph of $h_-$ or $h_+$. The corresponding curve $\gamma_0$ is thus the concatenation of an arc of circle of curvature $\pm \kappa_0$, a line segment and another arc of circle of curvature $\pm \kappa_0$, though some of these may degenerate to a point. It is an immediate consequence of (3.6) that $\gamma_0$ (and hence $f_0$) is independent of $\gamma$ and of the chosen axis $\varphi$.

(3.10) **Lemma.** Let $\varphi$ be an axis of $\gamma \in \hat{U}_c$ and $s \mapsto \gamma_s \ (s \in [0, 1])$ be the deformation described in (3.8). Then $\gamma_0 \in \hat{U}_c$ is the unique curve of minimal length in $\hat{L}_{-\kappa_0}^{+\kappa_0}(Q)$. □

**Remark.** Notice that this proves Dubins’ Theorem I [1957] in the case where $\hat{L}_{-\kappa_0}^{+\kappa_0}(Q)$ contains condensed curves. Furthermore, given $Q$ and $\kappa_0$, we can use (3.8) to describe $\gamma_0$ explicitly.

(3.11) **Lemma.** Let $S_+ = \{x \in [0, b] : f(x) \geq \mu_0\}$ and $S_- = \{x \in [0, b] : f(x) \leq \mu_0\}$. Then $f_s(x)$ is an increasing (resp. decreasing) function of $s$ if $x \in S_+$ (resp. $S_-$). Moreover, for all $s \in [0, 1]$, $f_s(x) \geq \mu_0$ if $x \in S_+$ and $f_s(x) \leq \mu_0$ if $x \in S_-$.

**Proof.** Suppose that $x \in S_+$. From (26) and (30), we deduce that

$$g_-(x), h_-(x), \mu_-(s) \leq f(x) \leq g_+(x), h_+(x).$$

Hence, $f_s(x) = \min(\mu_+(s), f(x)) \geq \mu_0$ and $f_s(x)$ increases with $s$ since $\mu_+(s)$ does. The proof for $x \in S_-$ is analogous. □

(3.12) **Corollary.** Let $m_- (s) = \inf_{x \in [0, b]} f_s(x)$ and $m_+ (s) = \sup_{x \in [0, b]} f_s(x)$. Then $m_+(s)$ is an increasing and $m_-(s)$ a decreasing function of $s \in [0, 1]$. □

(3.13) **Lemma.** Let $\gamma \in \hat{U}_c$ and $s \mapsto \gamma_s \in \hat{L}_{-\kappa_0}^{+\kappa_0}(Q; \theta_1)$ be the homotopy described in (3.8). Let $\omega_s$ denote the amplitude of $\gamma_s$. Then $\omega_s$ is an increasing function of $s$; in particular, $\gamma_s$ is condensed (i.e., $\gamma_s \in \hat{U}_c$) for all $s \in [0, 1]$.

**Proof.** Let $\varphi$ be the axis of $\gamma$ chosen for the construction. Recall that, by definition,

$$\omega_s = \sup_{x \in [0, b]} \theta_s(x) - \inf_{x \in [0, b]} \theta_s(x) \ (s \in [0, 1]),$$

where $\theta_s$ is the argument of $t_{\gamma_s}$ such that $\theta_s(0) = 0$. By (29),

$$f_s(x) = \tan(\theta_s(x) - \varphi).$$

Because the tangent is an increasing function, (3.12) immediately implies that $\omega_s$ is increasing. □
Remark. Although $\gamma_0$ has minimal amplitude in $\hat{U}_c$ by the previous lemma, there may be other curves in $\hat{U}_c$ with the same amplitude. This is the case, for instance, for the curves $\gamma_0$ and $\gamma$ corresponding to the functions $f$ and $f_0$ of Figure 4.

(3.14) Lemma. Let $\gamma \in \hat{U}_c$ and $s \mapsto \gamma_s$ be the deformation described in (3.8). Then the length of $\gamma_s$ is an increasing function of $s \in [0, 1]$.

Proof. Let $\lambda : \mathbb{R} \to \mathbb{R}$ be given by $\lambda(u) = (1 + u^2)^{1/2}$. A straightforward computation shows that
\begin{equation}
\lambda''(u) = (1 + u^2)^{-3/2} > 0 \quad \text{for all } u \in \mathbb{R}.
\end{equation}
Moreover, by the definition (29), the length $L_s$ of $\gamma_s$ is given by
$$L_s = \int_0^b (\lambda \circ f_s)(x) \, dx.$$ 

Let $s_1 \leq s_2 \in [0, 1]$, $S_+, S_-$ be as in (3.11) and
\begin{align*}
T_+ &= \{(x, y) \in [0, b] \times \mathbb{R} : f_{s_1}(x) \leq y \leq f_{s_2}(x)\}, \\
T_- &= \{(x, y) \in [0, b] \times \mathbb{R} : f_{s_2}(x) \leq y \leq f_{s_1}(x)\}.
\end{align*}
Using (3.11), we deduce that
\begin{align*}
L_{s_2} - L_{s_1} &= \int_0^b (\lambda \circ f_{s_2})(x) - (\lambda \circ f_{s_1})(x) \, dx \\
&= \left(\int_{S_+} + \int_{S_-}\right) (\lambda \circ f_{s_2})(x) - (\lambda \circ f_{s_1})(x) \, dx \\
&= \left(\int_{T_+} - \int_{T_-}\right) \lambda'(y) \, dy \, dx \\
&\geq \left(\int_{T_+} - \int_{T_-}\right) \lambda' (\mu_0) \, dy \, dx \quad \text{(by (33))} \\
&= \lambda' (\mu_0) \left(\int_0^b f_{s_2} - \int_0^b f_{s_1}\right) = 0 \quad \text{(by the definition of $f_s$).}
\end{align*}
Therefore, $L_s$ is an increasing function of $s \in [0, 1]$. $\square$

We are finally ready to prove (3.4) and (3.3).

Proof of (3.4). For each $\gamma \in \hat{U}_c$, let
\begin{equation}
\bar{\varphi}_\gamma = \frac{1}{2} \left( \sup_{t \in [0, 1]} \theta_\gamma(t) + \inf_{t \in [0, 1]} \theta_\gamma(t) \right),
\end{equation}
where $\theta_\gamma : [0, 1] \to \mathbb{R}$ is the argument of $t_\gamma$ satisfying $\theta_\gamma(0) = 0$. It is clear that $\bar{\varphi}_\gamma$ depends continuously on $\gamma \in \hat{U}_c$. Define $H : [0, 1] \times \hat{U}_c \to \hat{U}_c$ by $H(s, \gamma) = \gamma_s$, where $\gamma_s$ is the curve (29) constructed in (3.8) with chosen axis $\bar{\varphi}_\gamma$. Then part (ii) of (3.4) follows from (3.13), and part (iii) from (3.14). The last assertion of (3.4) and part (i) were established in (3.9). $\square$
Proof of (3.3). Assume that $\mathcal{U}_c$ is nonempty. It is certainly open in $\mathcal{L}^{+1}_{-1}(Q; \theta_1)$. Hence, by (1.7), it suffices to prove that $\mathcal{U}_c$ is weakly contractible. Let $K$ be a compact manifold and $g : K \to \mathcal{U}_c$, $a \mapsto \gamma^a$, be a continuous map. Using (1.11), we may assume that the image of $g$ is contained in (the image under set inclusion of) $C^+_{-\kappa_0}(Q; \theta_1)$ for some $\kappa_0 \in (0, 1)$. By (1.17), we have continuous injections

$$C^+_{-\kappa_0}(Q; \theta_1) \to \hat{\mathcal{L}}^+_{-\kappa_0}(Q; \theta_1) \to \mathcal{L}^+_{-1}(Q; \theta_1).$$

Let $G : [0, 1] \times K \to \mathcal{L}^{+1}_{-1}(Q; \theta_1)$ map $(s, a)$ to (the image under set inclusion of) $H(s, \gamma^a)$, with $H$ as in (3.4). Then $G$ is a null-homotopy of $g$ in $\mathcal{U}_c$. \hfill \Box

The next couple of lemmas will only be needed in later sections.

(3.15) Lemma. Suppose that there exists $\hat{\omega} \in (0, \pi)$ such that if $\gamma \in \hat{\mathcal{U}}_c \subset \hat{\mathcal{L}}^+_{-\kappa_0}(Q; \theta_1)$ then its amplitude $\omega_{\gamma}$ satisfies $\omega_{\gamma} \leq \hat{\omega}$. Let $L(\eta)$ denote the length of $\eta$. Then $\sup_{\gamma \in \hat{\mathcal{U}}_c} L(\gamma)$ is finite. In particular, the images of $\gamma \in \hat{\mathcal{U}}_c$ are all contained in some bounded subset of $\mathbb{C}$.

Proof. Let $\gamma \in \hat{\mathcal{U}}_c$ and $\bar{\varphi}_\gamma$ be as in (34). By hypothesis, the image of $\theta_\gamma : [0, 1] \to \mathbb{R}$ is contained in $[\bar{\varphi}_\gamma - \hat{\omega}/2, \bar{\varphi}_\gamma + \hat{\omega}/2]$. Let $f : [0, b] \to \mathbb{R}$ be the function corresponding to $\gamma$ and the axis $\bar{\varphi}_\gamma$, in the notation of (3.8). Note that $b = (e^{i\bar{\varphi}_\gamma}, q) \leq |q|$, where $q$ is the $\mathbb{C}$-coordinate of $Q$. By (32),

$$|f(x)| \leq \tan\left(\frac{\hat{\omega}}{2}\right) \quad \text{for all } x \in [0, b].$$

Therefore, the length $L(\gamma)$ of $\gamma$ satisfies

$$L(\gamma) = \int_0^b \sqrt{1 + f(x)^2} \, dx \leq b \sec\left(\frac{\hat{\omega}}{2}\right) \leq |q| \sec\left(\frac{\hat{\omega}}{2}\right). \hfill \Box$$

(3.16) Lemma. Let $\hat{\mathcal{U}}_c \subset \hat{\mathcal{L}}^+_{-\kappa_0}(Q; \theta_1)$ and $H : [0, 1] \times \hat{\mathcal{U}}_c \to \hat{\mathcal{U}}_c$ be the deformation described in (3.4) and (3.8). Suppose that $\theta_1 = 0$. Then $\omega_0 < \omega_1$ unless $\gamma_1 = \gamma_0$.

Proof. It is obvious that $\omega_1 = \omega_0$ if $\gamma_1 = \gamma_0$. The condition $\theta_1 = 0$ is equivalent to $r_0 = r_b$, in the notation of (3.8). Suppose without loss of generality that $\mu_0 \geq r_0$, so that $m_+(0) = \mu_0$.

If $m_+(1) \leq \mu_0$, then $S_- = [0, b]$. Hence, by (3.11), $f_1(x) \leq f_0(x)$ for all $x \in [0, b]$. Since $f_1$ and $f_0$ have the same area, we conclude that $f_1 = f_0$, that is, $\gamma_1 = \gamma_0$.

By (3.12), $m_-(1) \leq m_-(0)$. Hence, if $m_+(1) > \mu_0 = m_+(0)$, then $\omega_0 < \omega_1$ by (31) and (32). \hfill \Box

Existence of condensed curves. The question of whether $\mathcal{U}_c \neq \emptyset$ is settled by means of an elementary geometric construction. In all that follows, $C_r(a)$ denotes the circle of radius $r > 0$ centered at $a \in \mathbb{C}$.
Let $\theta_1 \in [0, \pi)$ be fixed and $Q = (q, z)$, where $z = e^{i\theta_1}$. There exist condensed curves in $\mathcal{L}_{-1}^+ (Q; \theta_1)$ if and only if $q$ belongs to the open gray region.

**Figure 5.** Let $\theta_1 \in [0, \pi)$ be fixed and $Q = (q, z)$, where $z = e^{i\theta_1}$. There exist condensed curves in $\mathcal{L}_{-1}^+ (Q; \theta_1)$ if and only if $q$ belongs to the open gray region.

**Proposition.** Let $\theta_1 \in [0, \pi)$ be fixed, $z = e^{i\theta_1}$ and $Q = (q, z) \in \mathbb{C} \times S^1$. Let $R_{U_c}$ be the open region of the plane which does not contain $-i + iz$ and which is bounded by the shortest arcs of the circles $C_2(\pm(i + iz))$ joining $i - iz$ to $i - iz \pm 2(i + iz)$ and their tangent lines at the latter points. Then $\mathcal{L}_{-1}^+ (Q; \theta_1)$ contains condensed curves if and only if $q \in R_{U_c}$. (See Figure 5.)

It is clear from the definition of condensed curve that $U_c \subset \mathcal{L}_{-1}^+ (Q; \theta_1)$ is empty if $|\theta_1| \geq \pi$. In other words, all condensed curves in $\mathcal{L}_{-1}^+ (Q)$ must be contained in the subspace $\mathcal{L}_{-1}^+ (Q; \theta_1)$ with $\theta_1$ the unique number in $(-\pi, \pi)$ satisfying $e^{i\theta_1} = z$ (for $z \neq -1$). We have assumed that $\theta_1 \in [0, \pi)$ just to simplify the statement. If $\theta_1 \in (-\pi, 0]$, the only difference is that $i - iz$ should be interchanged with $-i + iz$. The proof is analogous to the one given below. Alternatively, it can be deduced from the proposition by applying a reflection across the $x$-axis. When $\theta_1 = 0$, the statement becomes ambiguous; in this case the arcs of circles which
The curves which we have described have curvature equal to \( \pm 1 \) over intervals of positive measure and, additionally, may be critical curves. Nevertheless, for any \( q \in R_{U_c} \), we can find a condensed \( \gamma \in \mathcal{L}_{-1}^+ (Q; \theta_1) \) by composing one of these

\textbf{Proof of (3.17).} Let \( \eta : [0, 1] \to \mathbb{C} \) be condensed and let \( \theta_\eta : [0, 1] \to \mathbb{R} \) be the argument of \( t_\eta \) satisfying \( \theta_\eta (0) = 0 \). Observe that

\[
\inf \{ \theta_\eta (t) : t \in [0, 1] \} \in [\theta_1 - \pi, 0] \quad \text{and} \quad \sup \{ \theta_\eta (t) : t \in [0, 1] \} \in [\theta_1, \pi].
\]

The proof relies on the study of the following curves. For each \( \varphi \in [\theta_1, \pi] \), define \( \gamma^\varphi_\varphi : [0, 2\varphi - \theta_1] \to \mathbb{C} \) to be the unique curve parametrized by arc-length satisfying

\[
\gamma^\varphi_\varphi (0) = 0 \quad \text{and} \quad t_{\gamma^\varphi_\varphi} (s) = \begin{cases} 
\text{e}^{is} & \text{if } s \in [0, \varphi], \\
\text{e}^{i(2\varphi - s)} & \text{if } s \in [\varphi, 2\varphi - \theta_1].
\end{cases}
\]

Then \( \gamma^\varphi_\varphi \) is the concatenation of two arcs of circles of radius 1,

\[
\inf_{t \in [0,1]} \theta_{\gamma^\varphi_\varphi} (t) = 0, \quad \sup_{t \in [0,1]} \theta_{\gamma^\varphi_\varphi} (t) = \varphi, \quad t_{\gamma^\varphi_\varphi} (2\varphi - \theta_1) = z,
\]

\[
\gamma^\varphi_\varphi (2\varphi - \theta_1) = \int_0^\varphi \text{e}^{is} \, ds + \int_{\varphi}^{2\varphi - \theta_1} \text{e}^{i(2\varphi - s)} \, ds = (i + iz) - 2i e^{i\varphi}.
\]

Thus, as \( \varphi \) increases from \( \theta_1 \) to \( \pi \), the endpoints of the \( \gamma^\varphi_\varphi \) trace out the arc of \( C_2 (i + iz) \) bounded by \( i - iz \) and \( 3i + iz \). Further, the tangent line to \( C_2 (i + iz) \) at \( \gamma^\varphi_\varphi (2\varphi - \theta_1) \) is parallel to \( e^{i\varphi} \), for it must be orthogonal to \(-2i e^{i\varphi}\).

Similarly, for each \( \psi \in [\theta_1 - \pi, 0] \), let \( \gamma^-_\psi : [0, \theta_1 - 2\psi] \to \mathbb{C} \) be the curve, parametrized by arc-length, which satisfies

\[
\gamma^-_\psi (0) = 0 \quad \text{and} \quad t_{\gamma^-_\psi} (s) = \begin{cases} 
\text{e}^{-is} & \text{for } s \in [0, -\psi], \\
\text{e}^{i(2\psi + s)} & \text{for } s \in [-\psi, \theta_1 - 2\psi].
\end{cases}
\]

Then \( \gamma^-_\psi \) is the concatenation of two arcs of circles of radius 1, \( t_{\gamma^-_\psi} (\theta_1 - 2\psi) = z \) for all \( \psi \in [\theta_1 - \pi, 0] \), and as \( \psi \) decreases from 0 to \( \theta_1 - \pi \), the endpoints of the \( \gamma^-_\psi \) traverse the arc of \( C_2 (-i - iz) \) bounded by \( i - iz \) and \( -i - 3iz \). Moreover, the tangent line to this circle at \( \gamma^-_\psi (\theta_1 - 2\psi) \) is parallel to \( e^{i\psi} \).

Any \( q \in \overline{R}_{U_c} \) is the endpoint of a curve of one of the following three types:

(i) The concatenation of a \( \gamma^\varphi_\varphi \) or a \( \gamma^-_\psi \) with a line segment of direction \( z \).

(ii) The concatenation of \( \gamma^\varphi_\varphi \mid_{[0,\pi]} \), a line segment of length \( \ell \geq 0 \) having direction \(-1\), the arc \(-\ell + \gamma^\varphi_\varphi \mid_{[\pi,2\pi-\theta_1]} \), and a line segment of direction \( z \).

(iii) The concatenation of \( \gamma^-_\psi \mid_{[0,\pi-\theta_1]} \), a line segment of length \( \ell_1 \geq 0 \) of direction \(-z\), the arc \(-\ell_1 z + \gamma^-_\psi \mid_{[\pi-\theta_1,3\pi/2-\theta_1]} \), a line segment of length \( \ell_2 \geq 0 \) and direction \(-iz\), the arc \(-\ell_1 z - \ell_2 iz + \gamma^\varphi_\varphi \mid_{[3\pi/2-\theta_1,2\pi-\theta_1]} \), and a line segment of direction \( z \).

The curves which we have described have curvature equal to \( \pm 1 \) over intervals of positive measure and, additionally, may be critical curves. Nevertheless, for any \( q \in R_{U_c} \), we can find a condensed \( \gamma \in \mathcal{L}_{-1}^+ (Q; \theta_1) \) by composing one of these
curves with a dilatation through a factor $c > 1$, with $c$ close to 1 if $q$ lies close to $\partial R_{U\mathcal{C}}$, and by avoiding the argument $\pi$ (for a curve of type (i)) or $\theta_1 - \pi$ (for a curve of type (iii)).

Conversely, suppose that $\mathcal{L}^+_1(Q)$ contains condensed curves. Let $\eta : [0, L] \to \mathbb{C}$ be such a curve, parametrized by arc-length, and let $\varphi = \sup \theta$, where $\theta : [0, L] \to \mathbb{R}$ is an argument of $t_\eta$ satisfying $\theta(0) = 0$. Define

$$g : [0, L] \to \mathbb{R} \quad \text{by} \quad g(s) = (\eta(s) - \gamma^+_{\varphi}(2\varphi - \theta_1), ie^{i\varphi}).$$

Note that $g(s) > 0$ if and only if $\eta(s)$ lies to the left of the line through $\gamma^+_{\varphi}(2\varphi - \theta_1) \in C_2(i + iz)$ having direction $e^{i\varphi}$; we have already seen that this line is tangent to this circle at this point. We claim that $g(L) < 0$. Since $\eta$ is admissible, $\theta = \arg \circ t_\eta$ is an absolutely continuous function, and $|\theta'| = |\kappa_\eta| < 1$ almost everywhere by (5). Moreover, $\theta(s) \in [\varphi - \pi, \varphi]$ for all $s$ because $\eta$ is condensed. Hence,

$$(35) \quad g'(s) = \langle e^{i\theta(s)}, ie^{i\varphi} \rangle = \cos(\theta(s) - \varphi - \frac{\pi}{2}) \leq 0 \quad \text{for all} \ s \in [0, L].$$

Let $J_i = (a_i, b_i) \subset (0, L) (i = 1, 2, 3)$ be disjoint intervals such that

(I) $\theta(a_1) = 0$ and $\theta(b_1) = \theta_1$;

(II) $\theta(a_2) = \theta_1$ and $\theta(b_2) = \varphi$;

(III) $\theta(a_3) = \varphi$ and $\theta(b_3) = \theta_1$.

Such intervals exist because $\theta$ is a continuous function satisfying $\theta(0) = 0, \theta_1 \leq \varphi = \sup \theta$ and $\theta(L) = \theta_1$. Let $\lambda$ denote the Lebesgue measure on $\mathbb{R}$. Fix $i$ and let $[\alpha, \beta]$ be any nondegenerate subinterval of $\theta((a_i, b_i))$. Since $\theta$ is strictly 1-Lipschitz, if $S = \{s \in (a_i, b_i) : \alpha \leq \theta(s) \leq \beta\}$, then $\lambda(S) > \beta - \alpha$. Combining this with (35), we deduce that

$$g(L) - g(0) \leq \left( \int_{a_1}^{b_1} + \int_{a_2}^{b_2} + \int_{a_3}^{b_3} \right) g'(s) \, ds$$

$$< \int_0^{\theta_1} \langle e^{it}, e^{i\varphi} \rangle \, dt + 2 \int_{\theta_1}^{\varphi} \langle e^{it}, e^{i\varphi} \rangle \, dt = \langle \gamma^+_{\varphi}(2\varphi - \theta_1), ie^{i\varphi} \rangle.$$ 

Therefore, $g(L) < 0$ as claimed. Similarly, if $\psi = \inf \theta$, then $\eta(L)$ lies on the side of the tangent to $C_2(-i - iz)$ at $\gamma^-_{\varphi}(\theta_1 - 2\psi)$ which does not contain $-i + iz$. It follows that $q = \eta(L) \in R_{U\mathcal{C}}$.

\[\square\]

4. Topology of $U_d$

Throughout this section, let $K$ denote a compact manifold, possibly with boundary. Also, let $Q = (q, z) \in \mathbb{C} \times S^1$ be fixed (but otherwise arbitrary) and let $U_d \subset \mathcal{L}_{-1}(Q; \theta_1)$ denote the subset consisting of all diffuse curves in $\mathcal{L}_{-1}(Q)$ having total turning $\theta_1$, for some fixed $\theta_1 \in \mathbb{R}$ satisfying $e^{i\theta_1} = z$. Finally, let $O = (0, 1) \in \mathbb{C} \times S^1$, the identity element of the group $UT\mathbb{C}$.
Our next objective is to prove that $\mathcal{U}_d$ is contractible. The idea behind the proof is quite simple. If $\gamma$ is diffuse, then we can “graft” a straight line segment of length greater than 4 onto $\gamma$, as illustrated in Figure 8. By the theorem of Dubins stated in the introduction, this segment can be deformed so that in the end an eight curve of large radius traversed $n$ times has been attached to it, as in Figure 7(e). These eights are then spread along the curve, as in Figure 7(f). If $n \in \mathbb{N}$ is large enough, the spreading can be carried out within $L^{+1}_{-1}(Q)$. The result is a curve which is so loose that the constraints on the curvature may be safely forgotten, allowing us to use the following fact.

(4.1) Theorem (Smale). Let $Q = (q, z) \in \mathbb{C} \times S^1$. Then $C^{+\infty}_{-\infty}(Q)$ and $L^{+\infty}_{-\infty}(Q)$ have $\aleph_0$ connected components, one for each $\theta_1 \in \mathbb{R}$ satisfying $e^{i\theta_1} = z$, all of which are contractible.

Proof. For the space $C^{+\infty}_{-\infty}(Q)$, the proof was discussed in the introduction. We may replace $C^{+\infty}_{-\infty}(Q)$ by $L^{+\infty}_{-\infty}(Q)$ using (1.12). \hfill $\square$

(4.2) Lemma. Let $P \in UT\mathbb{C}$. Then $C^{+1}_{-1}(P, P)$ and $L^{+1}_{-1}(P, P)$ have $\aleph_0$ connected components, one for each turning number $n \in \mathbb{Z}$, all of which are contractible.

Proof. By (1.12), it suffices to prove the result for $C^{+1}_{-1}(P, P)$. Let $\mathcal{C}_n \subset C^{+1}_{-1}(P, P)$ denote the subset of all curves which have turning number $n$. Then each $\mathcal{C}_n$ is closed and open. Hence, to establish that $\mathcal{C}_n$ is a contractible component, it suffices, by (1.7)(b), to prove that it is weakly contractible.

Recall that $C^{+1}_{-1}(P, P) \approx C^{+1}_{-1}(O)$, the homeomorphism coming from composing all curves with a suitable Euclidean motion. We may thus assume that $P = O$. Let $K$ be a compact manifold and $f : K \to \mathcal{C}_n$ a continuous map. By (4.1), there exists a continuous $F : [0, 1] \times K \to C^{+\infty}_{-\infty}(O)$ such that $F_0 = f$ and $F_1$ is a constant map. Let

$$M = 2 \sup \{|\kappa_{F(s, a)}(t)| : s, t \in [0, 1], a \in K\}.$$

Given a curve $\gamma$, let $M_\gamma$ denote the dilated curve $t \mapsto M_\gamma(t)$. It is easy to see that $\kappa_{M_\gamma} = \kappa_\gamma/M$. Hence, $MF$ is a homotopy between $Mf$ and a constant map within $C^{+1}_{-1}(O)$. But $f$ and $Mf$ are homotopic within $C^{+1}_{-1}(O)$ through $u \mapsto uf$ ($u \in [1, M]$). Therefore, $f$ is null-homotopic. \hfill $\square$

Loops and eights. We shall now explain how to attach loops and eights to a curve, and how to spread eights along it (Figure 7).

(4.3) Definition. We denote by $\alpha : \mathbb{R} \to \mathbb{C}$ the loop of radius 2 and by $\beta : \mathbb{R} \to \mathbb{C}$ the eight curve of the same radius (see Figure 7(b) and (d)) given by

$$\alpha(t) = 2i(1 - \exp(2\pi it)),$$

$$\beta(t) = \begin{cases} 
\alpha(2t) & \text{for } t \in \left[\frac{m}{2}, \frac{m+1}{2}\right], m \equiv 0 \text{ (mod 2)}, \\
-\alpha(-2t) & \text{for } t \in \left[\frac{m}{2}, \frac{m+1}{2}\right], m \equiv 1 \text{ (mod 2)}
\end{cases} \quad (m \in \mathbb{Z}).$$
We shall also denote by \( \alpha_n : [0, 1] \to \mathbb{C} \) (resp. \( \beta_n : [0, 1] \to \mathbb{C} \)) a loop (resp. eight) traversed \( n \geq 1 \) times: \( \alpha_n(t) = \alpha(nt) \) and \( \beta_n(t) = \beta(nt) \) \( (t \in [0, 1]) \).

Note that \( \alpha_n, \beta_n \in \mathcal{L}^{+1}_-(O) \). The curvature of \( \alpha_n \) is everywhere equal to \( \frac{1}{2} \), and that of \( \beta_n \) equals \( \pm \frac{1}{2} \) except at the \( 2n - 1 \) points where it is undefined. The turning number of \( \alpha_n \) is \( n \), and that of \( \beta_n \) is \( 0 \).

(4.4) Definition. Let \( t_0 \in (0, 1), 0 < 2\varepsilon < \min\{1 - t_0, t_0\}, 1 \leq n \in \mathbb{N} \) and \( \gamma \) be an admissible plane curve. Define piecewise linear functions \( \phi, \psi : [0, 1] \to [0, 1] \) (whose graphs are depicted in Figure 6) by

\[
\phi(t) = \begin{cases} 
  t & \text{if } t \notin [t_0 - 2\varepsilon, t_0 + 2\varepsilon], \\
  2t - t_0 + 2\varepsilon & \text{if } t \in [t_0 - 2\varepsilon, t_0 - \varepsilon], \\
  t_0 & \text{if } t \in [t_0 - \varepsilon, t_0 + \varepsilon], \\
  2t - t_0 - 2\varepsilon & \text{if } t \in [t_0 + \varepsilon, t_0 + 2\varepsilon],
\end{cases}
\]

\[
\psi(t) = \begin{cases} 
  0 & \text{if } t \in [0, t_0 - \varepsilon], \\
  (t - t_0 + \varepsilon)/2\varepsilon & \text{if } t \in [t_0 - \varepsilon, t_0 + \varepsilon], \\
  1 & \text{if } t \in [t_0 + \varepsilon, 1].
\end{cases}
\]

Define curves \( A_{\gamma,n,t_0}, B_{\gamma,n,t_0} \) (attaching loops, eights) and \( S_{\gamma,n} : [0, 1] \to \mathbb{C} \) (spreading eights) by (see Figure 7)

\[
A_{\gamma,n,t_0}(t) = \Phi_{\gamma}(\phi(t))\alpha_n(\psi(t)), \\
B_{\gamma,n,t_0}(t) = \Phi_{\gamma}(\phi(t))\beta_n(\psi(t)), \quad (t \in [0, 1]). \\
S_{\gamma,n}(t) = \Phi_{\gamma}(t)\beta_n(t)
\]

Here \( \Phi_{\gamma} : [0, 1] \to \mathbb{C} \times \mathbb{S}^1 \) is the frame of \( \gamma \) (as in (1)), but viewed as a curve in the group \( UT\mathbb{C} \): each \( \Phi_{\gamma}(t)a = \gamma(t) + t\gamma(t)a \) for \( a \in \mathbb{C} \). Different values of \( \varepsilon \) and \( t_0 \) yield curves which are homotopic in whichever space one is working with.
Figure 7. A depiction of how to attach loops and eights to a curve and how to spread eights along it.

(4.5) Lemma. Let $t_0 \in (0, 1)$, $1 \leq n \in \mathbb{N}$ and $\gamma$ be an admissible plane curve. Then:

(a) $A_{\gamma,n,t_0}$, $B_{\gamma,n,t_0}$ and $S_{\gamma,n}$ have the same initial and final frames as $\gamma$.

(b) $B_{\gamma,n,t_0}$ and $S_{\gamma,n}$ lie in the same connected component of $\mathcal{L}^{+\infty}_{-\infty}(P, Q)$ ($P=\Phi(0)$, $Q = \Phi(1)$).

(c) If $\gamma \in \mathcal{L}^{+1}_{-1}(P, Q)$, then $A_{\gamma,n,t_0}$, $B_{\gamma,n,t_0} \in \mathcal{L}^{+1}_{-1}(P, Q)$ also.

(d) Let $O = (0, 1) \in \mathbb{C} \times S^1$. Then $\alpha_1$ and $B_{\alpha_1,n,t_0}$ lie in the same connected component of $\mathcal{L}^{+1}_{-1}(O)$ for all $n \geq 1$.

(e) If $f$, $g : K \to \mathbb{U}_d$ are continuous and homotopic within $\mathbb{U}_d$, then so are $B_{f,n,t_0}$ and $B_{g,n,t_0}$.

(f) If $\gamma$ is a reparametrization of $\alpha_1$, then $A_{\gamma,n,t_0}$ is a reparametrization of $\alpha_{n+1}$.

Proof. It is clear that $A_{\gamma,n,t_0}$, $B_{\gamma,n,t_0}$ have the same initial and final frames as $\gamma$, since they agree with $\gamma$ in neighborhoods of the endpoints of $[0, 1]$. From the definition of $S_{\gamma,n}$, we find that

$$\dot{S}_{\gamma,n} = \dot{\gamma} + \dot{t}_\gamma \beta_n + t_\gamma \dot{\beta}_n.$$  

Using that $\Phi_{\beta_n}(0) = \Phi_{\beta_n}(1) = (0, 1) \in \mathbb{C} \times S^1$, we deduce that

$$S_{\gamma,n}(0) = \gamma(0) \quad \text{and} \quad \dot{S}_{\gamma,n}(0) = (|\dot{\gamma}(0)| + |\dot{\beta}_n(0)|) t_\gamma(0).$$

Similarly, $S_{\gamma,n}(1) = \gamma(1)$ and $\dot{S}_{\gamma,n}(1)$ is a positive multiple of $t_\gamma(1)$. This establishes (a).
Let \( \phi, \psi : [0, 1] \to [0, 1] \) be as in (36), and set
\[
(37) \quad \phi_s(t) = (1 - s)\phi(t) + st \quad \text{and} \quad \psi_s(t) = (1 - s)\psi(t) + st \quad (s, t \in [0, 1]).
\]

Then
\[
(s, t) \mapsto \Phi_\gamma(\phi_s(t))\beta_n(\psi_s(t)) \quad (s, t \in [0, 1])
\]
defines a homotopy between \( B_{\gamma,n,t_0} \) and \( S_{\gamma,n} \) in \( \mathcal{L}_{-\infty}^{+\infty}(P, Q) \). This proves (b).

Part (c) follows from (a) and the fact that the curvatures of \( \alpha_n, \beta_n \) equal \( \pm \frac{1}{2} \) a.e.

Part (d) is a corollary of (4.2).

For part (e), let \( H : [0, 1] \times K \to \mathcal{U}_d \) be a continuous map with \( H_0 = f \) and \( H_1 = g \). Set
\[
\hat{H}(s, a)(t) = \Phi_{H(s,a)}(\phi(t))\beta_n(\psi(t)) \quad (s, t \in [0, 1], a \in K).
\]
Then \( \hat{H} \) is a homotopy between \( B_{f,n,t_0} = \hat{H}_0 \) and \( B_{g,n,t_0} = \hat{H}_1 \) in \( \mathcal{U}_d \).

Part (f) is obvious. \( \square \)

(4.6) Lemma. Let \( f : K \to \mathcal{C}^{+\infty}_{-\infty}(Q) \) be continuous. Then there exists \( n_0 \in \mathbb{N} \) such that \( S_{f(a),n} \in \mathcal{L}_1^{+1}(Q) \) for all \( a \in K \) whenever \( n \geq n_0 \) (\( n \in \mathbb{N} \)).

Proof. For \( a \in K \), let \( \gamma_a = f(a) \) and \( t_a = t_{\gamma_a} \). Let
\[
T = \left\{ \frac{1}{2n}, \frac{2}{2n}, \ldots, \frac{2n - 1}{2n} \right\}.
\]

Then,
\[
\begin{align*}
S_{\gamma_a,n}(t) &= \Phi_{\gamma_a}(t)\beta_n(t) = \gamma_a(t) + t_a(t)\beta(nt) \quad (t \in [0, 1], a \in K), \\
\dot{S}_{\gamma_a,n}(t) &= \dot{\gamma}_a(t) + \dot{t}_a(t)\beta(nt) + nt_a(t)\hat{\beta}(nt) \quad (t \in [0, 1], a \in K), \\
\ddot{S}_{\gamma_a,n}(t) &= \ddot{\gamma}_a(t) + \ddot{t}_a(t)\beta(nt) + 2nt_a(t)\hat{\beta}(nt) + n^2t_a(t)\hat{\beta}(nt) \quad (t \in [0, 1] \setminus T, a \in K).
\end{align*}
\]

Since \( f : K \to \mathcal{C}^{+\infty}_{-\infty}(Q) \) is continuous and \( K \) is compact, \( |\gamma_a^{(k)}(t)| \) and \( |t_a^{(k)}(t)| \) (\( k = 0, 1, 2 \)) are all bounded by some constant as \( (t, a) \) ranges over \([0, 1] \times K\). Using the third expression for the curvature in (4) and the multilinearity of the determinant, we conclude that
\[
\kappa_{\gamma_a,n}(t) = \frac{1}{2} + O\left(\frac{1}{n}\right) \quad (t \in [0, 1] \setminus T, a \in K),
\]
where \( O(1/n) \) is a function of \( (t, a) \) such that \( n|O(1/n)| \) is uniformly bounded over \([0, 1] \setminus T\) \( \times K \) as \( n \) ranges over \( \mathbb{N} \). It follows that \( S_{\gamma_a,n} \in \mathcal{L}_1^{+1}(Q) \) for all sufficiently large \( n \). \( \square \)

(4.7) Lemma. Let \( f : K \to \mathcal{C}^{+\infty}_{-1}(Q) \) be continuous, \( t_0 \in (0, 1) \). Then for all sufficiently large \( n \in \mathbb{N} \), there exists a continuous \( H : [0, 1] \times K \to \mathcal{L}_1^{+1}(Q) \) with \( H_0 = B_{f,n,t_0} \) and \( H_1 = S_{f,n} \).
Proof. Let $H$ be given by

$$H(s, a)(t) = \Phi_{f(a)}(\phi_s(t)) \beta_n(\psi_s(t)) \quad (s, t \in [0, 1], a \in K),$$

where $\phi_s, \psi_s$ are as in (37). Then $H(0, a) = B_{f(a), n, t_0}$ and $H(1, a) = S_{f(a), n}$.

A computation entirely similar to the one in the proof of (4.6) establishes that $H(s, a) \in \mathcal{L}_{-1}^{+1}(Q)$ for all $s \in [0, 1], a \in K$ if $n$ is sufficiently large. The details will be left to the reader, but to make things easier, notice that $\phi_s, \psi_s$ are piecewise linear for all $s \in [0, 1]$, so that $\dot{\psi}_s = \dot{\phi}_s = 0$ except at a finite set of points (which depends on $s$).

The next result provides a sufficient condition, which does not involve $g$, for one to be able to write a compact family of curves $f$ as $f = A_{g, n, t_0}$.

(4.8) Lemma. Let $X$ be a compact Hausdorff topological space and

$$f : X \to \mathcal{U}_d \subset \mathcal{L}_{-1}^{+1}(Q; \theta_1), \quad t_0 : X \to (0, 1)$$

be continuous maps. Then it is possible to reparametrize each $f(a)$ (continuously with $a$) and find a continuous $g : X \to \mathcal{L}_{-1}^{+1}(Q; \theta_1)$ so that $f(a) = A_{g(a), n, t_0(a)}$ for all $a \in X$ if and only if there exists a continuous function $\varepsilon : X \to (0, 1)$ such that for all $a \in X$,

(i) $0 < t_0(a) - \varepsilon(a) < t_0(a) + \varepsilon(a) < 1$;

(ii) $f(a)|_{[t_0(a) - \varepsilon(a), t_0(a) + \varepsilon(a)]}$ is some parametrization of $\Phi_{f(a)}(t_0(a) - \varepsilon(a)) \alpha_n$.

Proof. Suppose that such a function $\varepsilon : X \to (0, 1)$ exists. Since $X$ is compact, we may reparametrize all $f(a)$ so that $\varepsilon$ becomes a constant function and, for all $a \in X$, satisfies

(I) $0 < t_0(a) - 2\varepsilon < t_0(a) + 2\varepsilon < 1$;

(II) $f(a)|_{[t_0(a) - \varepsilon, t_0(a) + \varepsilon]}$ is a parametrization of $\Phi_{f(a)}(t_0(a) - \varepsilon) \alpha_n$ by a multiple of arc-length.

Define $g : X \to \mathcal{L}_{-1}^{+1}(Q)$ by

$$g(a)(t) = \begin{cases} f(a)(t) & \text{if } t \notin [t_0(a) - 2\varepsilon, t_0(a) + 2\varepsilon], \\ f(a)\left(\frac{1}{2}(t + t_0(a) - 2\varepsilon)\right) & \text{if } t \in [t_0(a) - 2\varepsilon, t_0(a)], \quad (a \in X, t \in [0, 1]). \\ f(a)\left(\frac{1}{2}(t + t_0(a) + 2\varepsilon)\right) & \text{if } t \in [t_0(a), t_0(a) + 2\varepsilon] \end{cases}$$

Then $g$ is continuous because $f$ and $t_0$ are continuous, and $f(a) = A_{g(a), n, t_0(a)}$ for all $a \in X$. This proves the “if” part of the lemma. The converse is obvious.

As a simple application of (4.6), we prove that this article is not a study of the empty set.
(4.9) Lemma. Let \( \kappa_1 < \kappa_2 \), \( P = (p, w) \), \( Q = (q, z) \in \mathbb{C} \times \mathbb{S}^1 \) and let \( \theta_1 \in \mathbb{R} \) satisfy \( e^{i\theta_1} = z\bar{w} \). Then:

(a) \( \mathcal{L}^2_{\kappa_1}(P, Q) \neq \emptyset \).

(b) \( \mathcal{L}^2_{\kappa_1}(P, Q; \theta_1) \neq \emptyset \) if \( \kappa_1 \kappa_2 < 0 \).

(c) If \( \kappa_1 < \kappa_2 \leq 0 \), then \( \mathcal{L}^2_{\kappa_1}(P, Q; \theta_1) = \emptyset \) for all sufficiently large \( \theta_1 \). If \( 0 \leq \kappa_1 < \kappa_2 \), then \( \mathcal{L}^2_{\kappa_1}(P, Q; \theta_1) = \emptyset \) for all sufficiently small \( \theta_1 \).

Proof. By (2.6), we need only consider spaces of the form \( \mathcal{L}^+_{-1}(Q) \), \( \mathcal{L}^+\infty_{0}(Q) \) and \( \mathcal{L}^+\infty_{1}(Q) \). It is clear that \( \mathcal{C}^+\infty_{-1}(Q) \neq \emptyset \) for all \( Q \in UT\mathbb{C} \). Let \( \gamma \in \mathcal{C}^+\infty_{-1}(Q) \) be arbitrary.

By (4.6), if \( n \) is sufficiently large, then \( S_{\gamma,n} \in \mathcal{L}^+_{-1}(Q) \). Furthermore, attaching loops (possibly with reversed orientation) to \( S_{\gamma,n} \), we can obtain a curve in \( \mathcal{L}^+_{-1}(Q; \theta_1) \) for any \( \theta_1 \in \mathbb{R} \) satisfying \( e^{i\theta_1} = z \). This proves (b), and also part (a) when \( \kappa_1 \kappa_2 < 0 \).

Similarly, define a curve \( \tilde{S}_{\gamma,n} \) by \( \tilde{S}_{\gamma,n}(t) = \Phi_\gamma(t)\left(\frac{1}{2}n\alpha_n(t)\right) \) \( t \in [0, 1] \). In words, \( \tilde{S}_{\gamma,n} \) is obtained from \( \gamma \) by spreading \( n \) loops of radius \( \frac{1}{2} \), instead of \( n \) eights of radius 2. Using an argument analogous to the one which established (4.6), one sees that \( \tilde{S}_{\gamma,n} \in \mathcal{L}^+\infty_{1}(Q) \) for all sufficiently large \( n \). This completes the proof of (a).

To see that \( \mathcal{L}^2_{\kappa_1}(P, Q; \theta_1) \) may be empty if \( \kappa_1 \kappa_2 \geq 0 \), we use (5): if \( \kappa_1, \kappa_2 \) are both nonnegative, for example, then \( \mathcal{L}^2_{\kappa_1}(P, Q) \) can only contain curves having positive total turning. \( \square \)

Remark. Invoking (1.11), we obtain a version of (4.9) with \( \mathcal{C} \) in place of \( \mathcal{L} \).

(4.10) Corollary. Let \( \mathcal{U}_d \) denote the subset of \( \mathcal{L}^+_{-1}(Q; \theta_1) \) consisting of all diffuse curves, where \( Q = (q, z) \) and \( e^{i\theta_1} = z \). Then \( \mathcal{U}_d \neq \emptyset \).

Proof. Lemma (4.5)(c) implies that \( B_{\gamma,1,1/2} \in \mathcal{U}_d \) for any \( \gamma \in \mathcal{L}^+_{-1}(Q; \theta_1) \). Since the latter is nonempty by (4.9)(b), so is \( \mathcal{U}_d \). \( \square \)

(4.11) Theorem (Dubins). Let \( x > 0 \), \( Q = (x, 1) \) and \( \eta \in \mathcal{L}^+_{-1}(Q) \) be the line segment \( \eta : t \mapsto xt \). Then \( \eta \) and \( B_{\eta,1,1/2} \) lie in the same component of \( \mathcal{L}^+_{-1}(Q) \) if and only if \( x > 4 \).

Proof. See [Dubins 1961, Theorem 5.3]. \( \square \)

The next construction provides a homotopy of the straight line segment \([0, x]\) to the same segment with an eight attached which is continuous with respect to \( x \).

(4.12) Construction. For \( x > 0 \), let \( \eta_x : [0, x] \to \mathbb{C} \) be the line segment \( t \mapsto t \). Take \( t_0 = \frac{1}{2} \) in (36) and let \( h : [0, 1] \times [0, 6] \to \mathbb{C} \) be a fixed homotopy between \( h_0 = \eta_6 \) and \( h_1 = \Phi_{\eta_6} \left( 6 \phi \left( \frac{t}{6} \right) \right) \beta_1 \left( \psi \left( \frac{t}{6} \right) \right) \) (\( \eta_6 \) with an eight attached).
such that \( t \mapsto h_s(6t) \ (t \in [0, 1]) \) is a curve in \( \mathcal{L}^+_1(Q) \) for all \( s \in [0, 1] \). The existence of \( h \) is guaranteed by (4.11). Let \( \mu : [0, +\infty) \rightarrow [0, 1] \) be a smooth function such that \( \mu(x) = 0 \) if \( x \in [0, 6] \) and \( \mu(x) = 1 \) if \( x \geq 8 \). Define a family of curves \( \eta^u_x : [0, 1] \rightarrow \mathbb{C} \) by

\[
\eta^u_x(t) = \begin{cases} 
\eta_x(t) & \text{if } t \geq 6 \text{ or } x \leq 6, \\
h(u \mu(x), t) & \text{if } t \leq 6 \text{ and } x \geq 6
\end{cases}
\]

\((u \in [0, 1], t \in [0, x], x > 0)\).

Of course, \( \eta^0_x = \eta_x \) for all \( x > 0 \). If \( x \geq 8 \), then \( \eta^1_x \) equals \( \eta_x \) with an eight attached; in particular, \( \eta^1_x|_{[3-6\varepsilon,3]} \) is a loop.

**Grafting.** We now explain how to graft straight line segments onto a diffuse curve (see Figure 8).

(4.13) **Definition.** Let \( \gamma \in \mathcal{L}^+_1(Q) \) be a curve of length \( L \) parametrized by arc-length, \( \sigma_i \geq 0 \) and \( s_i \in [0, 1], i = 1, \ldots, 2n \), where the \( s_i \) form a nondecreasing sequence. Suppose that there exists a bijection \( p \) of \( \{1, \ldots, 2n\} \) onto itself such that for each \( i \),

\[
(*) \quad \sigma_{p(i)} = \sigma_i \quad \text{and} \quad t_\gamma(s_{p(i)}) = -t_\gamma(s_i).
\]

Then we define the graft \( G_\gamma = G_{\gamma, (s_i), (\sigma_i)} : [0, L + \sum_{i=1}^{2n} \sigma_i] \rightarrow \mathbb{C} \) by

\[
G_\gamma(s) = \begin{cases} 
\gamma(s) & \text{if } s \in [0, s_1], \\
\gamma(s_1)+(s-s_1)t_\gamma(s_1) & \text{if } s \in [s_1, s_1+\sigma_1], \\
\gamma(s-\sigma_1)+\sigma_1 t_\gamma(s_1) & \text{if } s \in [s_1+\sigma_1, s_1+\sigma_1+\sigma_2], \\
\vdots & \\
\gamma(s-\sum_{i=1}^{2n} \sigma_i)+\sum_{i=1}^{2n} \sigma_i t_\gamma(s_i) & \text{if } s \in [s_2n+\sum_{i=1}^{2n} \sigma_i, L+\sum_{i=1}^{2n} \sigma_i].
\end{cases}
\]

Although it simplifies the previous formula, the assumption that \( (s_i) \) is a nondecreasing sequence is not necessary for the construction to work, since we may always relabel the \( s_i \).

(4.14) **Lemma.** Let \( \gamma \in \mathcal{L}^+_1(Q) \) be diffuse and \( G_\gamma \) be as in (4.13). Then \( G_\gamma \) is parametrized by arc-length and lies in the same connected component of \( \mathcal{L}^+_1(Q) \) as \( \gamma \).

**Proof.** It is obvious from (39) that \( \Phi_{G_\gamma}(0) = \Phi_\gamma(0) \). Looking at the last line of (39) and using (\( *\)), we deduce that

\[
G_\gamma(s) = \gamma(s - \sum_{i=1}^{2n} \sigma_i) \quad \text{for } s \in \left[s_{2n} + \sum_{i=1}^{2n} \sigma_i, L + \sum_{i=1}^{2n} \sigma_i\right].
\]

Hence, \( \Phi_{G_\gamma}(L + \sum_{i=1}^{2n} \sigma_i) = \Phi_\gamma(L) \). Since \( G_\gamma \) is made up of line segments and arcs of \( \gamma \) (composed with translations), \( G_\gamma \in \mathcal{L}^+_1(Q) \). It is clear that \( G_\gamma \) is parametrized
Figure 8. A diffuse curve $\gamma$ and its graft $G_\gamma = G_{\gamma,(s_1,s_2,s_3,s_4),(\sigma_1,\sigma_2,\sigma_3,\sigma_4)}$.

by arc-length. Finally,

$$u \mapsto G_{\gamma,(s_i),(u\sigma_i)} (u \in [0, 1])$$

defines a path in $L_{-1}^{+1}(Q)$ joining $\gamma$ to $G_\gamma$. □

**Contractibility of $U_d$.** Recall that $K$ denotes a compact manifold, possibly with boundary.

(4.15) Lemma. Let $f : K \to U_d$ be continuous. Then there exist an open cover $(V_j)_{j=1}^m$ of $K$ and continuous maps $\tau^\pm_j : K \to (0, 1)$, $f_1 : K \to U_d$ such that

(i) $f \simeq f_1$ within $U_d$ and $f_1$ satisfies conditions (ii) and (iii) of (1.11).

(ii) $t_{f_1(a)}(\tau^+_j(a)) = -t_{f_1(a)}(\tau^-_j(a))$ whenever $a \in V_j$.

**Proof.** Apply (1.11) to $f$ and $U_d$ to obtain $f_1$. The idea is to use the implicit function theorem to find $\tau^\pm_j$. However, some care must be taken since $f_1$ need not be differentiable with respect to $a$.

For each $a \in K$, let $\theta_a : [0, 1] \to \mathbb{R}$ be the argument of $t_{f_1(a)}$ satisfying $\theta_a(0) = 0$, and set

$$\varphi_a = \frac{1}{2} \left( \sup_{t \in [0, 1]} \theta_a(t) + \inf_{t \in [0, 1]} \theta_a(t) \right).$$

Because each $\gamma_a$ is diffuse and $K$ is compact, we can find $\delta > 0$ such that

$$\theta_a([0, 1]) \supset \left( \varphi_a - \frac{\pi}{2} - \delta, \varphi_a + \frac{\pi}{2} + \delta \right) \quad \text{for all } a \in K.$$ 

Fix $a_0 \in K$. By Sard's theorem, we can find $\psi \in (\varphi_{a_0} + \pi/2, \varphi_{a_0} + \pi/2 + \delta)$ such that both $\psi$ and $\psi - \pi$ are regular values of $\theta_{a_0}$. Let $\tau^\pm(a_0) \in (0, 1)$ satisfy $\theta_{a_0}(\tau^+(a_0)) = \psi$ and $\theta_{a_0}(\tau^-(a_0)) = \psi - \pi$. No generality is lost in assuming that
\[ \dot{\theta}_a(\tau^+(a_0)) > 0. \] From (5), \( \dot{\theta}_a = |\dot{y}_{f(a)}| \kappa_{f(a)}. \) Thus, \( \dot{\theta}_a \) depends continuously on \( a \), so we can find \( \mu, \varepsilon > 0 \) and a compact neighborhood \( V \subset K \) of \( a_0 \) such that
\[ \psi \in \theta_a((\tau^+(a_0) - \varepsilon, \tau^+(a_0) + \varepsilon)) \quad \text{and} \quad \dot{\theta}_a(t) > \mu \]
whenever \( a \in V, |t - \tau^+(a_0)| < \varepsilon. \) Hence, for each \( a \in V \), there exists a unique \( \tau^+(a) \in (\tau^+(a_0) - \varepsilon, \tau^+(a_0) + \varepsilon) \) with \( \theta_a(\tau^+(a)) = \psi. \) We claim that the function \( \tau^+ : V \to (0, 1) \) so defined is continuous. Consider the equation
\[
\theta_a(\tau^+(b)) - \theta_a(\tau^+(a)) = (\theta_b(\tau^+(b)) - \theta_a(\tau^+(a))) + (\theta_a(\tau^+(b)) - \theta_b(\tau^+(b))) \quad (a, b \in V).
\]
The first term on the right side equals 0 by the definition of \( \tau^+ \), and the second converges to 0 as \( b \to a \) since \( \theta_b(t) \) is a uniformly continuous function of \( (b, t) \in K \times [0, 1]. \) Hence, by the mean value theorem,
\[
|\tau^+(b) - \tau^+(a)| < \frac{1}{\mu} |\theta_a(\tau^+(b)) - \theta_a(\tau^+(a))| \to 0 \quad \text{as} \quad b \to a \quad (a, b \in V).
\]
It follows that \( \tau^+ \) is continuous. Similarly, reducing \( V \) if necessary, we can find a continuous function \( \tau^- : V \to (0, 1) \) with \( \theta_a(\tau^-(a)) = \psi - \pi \) for all \( a \in V. \) To finish the proof, cover \( K \) by finitely many such compact neighborhoods \( V_j, \) let \( \tau_j^\pm : V_j \to (0, 1) \) be the corresponding functions and extend each \( \tau_j^\pm \) to \( K \) using the Tietze extension theorem. \( \square \)

**Lemma.** Let \( f : K \to \mathcal{U}_d \) be continuous. Then there exist an open cover \((W_j)_{j=1}^m\) of \( K \) and continuous maps \( t_j : K \to (0, 1), \ g_j : W_j \to \mathcal{L}^{+1}(Q) \) and \( f_2 : K \to \mathcal{U}_d \) such that

(i) \( f \simeq f_2 \) within \( \mathcal{U}_d; \)

(ii) \( f_2(a) = A_{g_j(a),1,t_j(a)} \) for all \( a \in W_j. \)

**Proof.** Take \( f_1 \) as in (4.15). By (1.15), we may assume that each map \( \gamma_a = f_1(a) : [0, L_a] \to \mathbb{C} \) is parametrized by arc-length, so that now \( \tau_j^\pm(a) \in (0, L_a) \) for each \( a. \) Let \((\lambda_j)_{j=1}^m\) be a partition of unity subordinate to \((V_j)_{j=1}^m\), with \( V_j \) as in (4.15). Set \( \sigma_j = 10m \lambda_j \) and \( W_j = \{a \in K : \sigma_j(a) > 8\}. \) Then \( W_j \subset V_j \) and the \( W_j \) form an open cover of \( K. \) Define
\[
\gamma_a^u = G_{\gamma_a, (\tau^-_1(a),...,\tau^-_m(a),\tau^+_1(a),...,\tau^+_m(a)),(u_1(a),...,u_{m_1}(a),u_{1}(a),...,u_{m_1}(a))} \quad (u \in [0, 1], a \in K)
\]
as in (4.13). Let us suppose that \( \tau^-_1 \leq \cdots \leq \tau^-_m(a) \leq \tau^+_1(a) \leq \cdots \leq \tau^+_m(a) \) for each \( a \) to abbreviate the notation, and set
\[
\xi_j^-(a) = \sum_{i \leq j} \sigma_i(a) \quad \text{and} \quad \xi_j^+(a) = 10m + \sum_{i \leq j} \sigma_i(a) \quad (a \in K, \ j = 1, \ldots, m).
\]
Then
\[
\gamma_a^1([\tau^-_j(a) + \xi_j^-(a), \tau^-_j(a) + \xi_j^-(a) + \sigma_j(a)])
\]
is a line segment, corresponding to the graft at $\gamma_a(\tau_j^-(a))$. Its length $\sigma_j(a)$ is at least 8 if $a \in \overline{W}_j$. Of course, the same statements hold with $^+$ instead of $^-$. We obtain $f_2$ by deforming all of these segments to eights. More precisely, for $u \in [1, 2]$ and $a \in K$, let

$$
\gamma^u_a(s) = \begin{cases} 
\Phi_{\gamma_0^u}(\tau_j^+(a) + \xi_j^+(a))\eta^{-1}_{q_j(a)}(s - \tau_j^+(a) - \xi_j^+(a)), & (s \in [0, \lambda_a + 20m]) \\
\gamma^1_a(s) & 
\end{cases}
$$

according to whether $s \in [\tau_j^+(a) + \xi_j^+(a), \tau_j^+(a) + \xi_j^+(a) + \sigma_j(a)]$ for some $j$ or not, respectively. Here $\eta^u_j$ is as in (4.12). Let $f_2 : K \to \mathbb{U}_d$ be given by $f_2(a) = \gamma^2_a$. Note that

$$
\gamma^2_a([\tau_j^+(a) + \xi_j^+(a) + 3 - 6\epsilon, \tau_j^+(a) + \xi_j^+(a) + 3]) \quad (j = 1, \ldots, m)
$$

is a loop whenever $a \in \overline{W}_j$. Thus (after reparametrizing the $\gamma^2_a$ so that their domains become $[0, 1]$), we may apply (4.8) to each family $f_2|_{\overline{W}_j}$ to find $g_j : \overline{W}_j \to \mathcal{L}_{-1}^{+1}(Q)$ and $t_j : \overline{W}_j \to (0, 1)$ such that

$$
f_2(a) = A_{g_j(a), 1, t_j(a)} \quad \text{for all } a \in W_j.
$$

The functions $t_j$ may be extended to all of $K$ by the Tietze extension theorem. \(\Box\)

(4.17) Lemma. Let $f : K \to \mathbb{U}_d$ be continuous. Suppose that there exist a covering of $K$ by open sets $W_j$ and continuous maps $t_j : K \to (0, 1)$, $g_j : W_j \to \mathcal{L}_{-1}^{+1}(Q)$ with $f(a) = A_{g_j(a), 1, t_j(a)}$ whenever $a \in W_j$, $j = 1, \ldots, m$. Then there exist continuous $g : K \to \mathcal{L}_{-1}^{+1}(Q)$ and $H : [0, 1] \times K \to \mathbb{U}_d$ with $H_0 = f$ and $H_1 = A_{g, 1, 1/2}$.

Proof. The proof will be by induction on $m$. If $m = 1$ then $W_1 = K$, and $H$ just slides the loop from $t_1$ to $\frac{1}{2}$:

$$
H(s, a) = A_{g_1(a), 1, (1-s) t_1(a)+s/2} \quad (s \in [0, 1], a \in K).
$$

Suppose now that $m > 1$. Let $W$ be an open set such that $\overline{W} \subset W_m$ and

$$
W_1 \cup \cdots \cup W_{m-1} \cup W = K.
$$

Let $\lambda : K \to [0, 1]$ be a continuous function such that $\lambda(a) = 1$ if $a \in W$ and $\lambda(a) = 0$ if $a \notin W_m$. Define $\hat{H} : [0, 1] \times K \to \mathbb{U}_d$ by

$$
\hat{H}(s, a) = \begin{cases} 
A_{g_m(a), 1, (1-\lambda(a)s) t_m(a)+\lambda(a) s t_{m-1}(a)} & \text{if } a \in W_m, \\
\hat{f}(a) & \text{if } a \notin W_m 
\end{cases} \quad (s \in [0, 1], a \in K).
$$

Then the induction hypothesis applies to $\hat{H}_1 : K \to \mathbb{U}_d$, the open sets $\hat{W}_i = W_i$ ($i = 1, \ldots, m - 2$) and $\hat{W}_{m-1} = W_{m-1} \cup W$, and the same functions $t_j$ as before, $j = 1, \ldots, m - 1$. The existence of $\hat{g}_m$ as in the statement is guaranteed by (4.8): using (4.5)(f), we deduce that there is at least one loop at $t_{m-1}(a)$ for $a \in \hat{W}_{m-1}$. \(\Box\)

(4.18) Proposition. Let $f : K \to \mathbb{U}_d$ be continuous. Then $f \simeq B_{f, n, 1/2}$ within $\mathbb{U}_d$ for all $n \geq 1$. 
Proof. Applying (4.16) and (4.17) to $f$, we obtain continuous maps $g : K \to \mathcal{L}^+_1(Q)$ and $h : K \to \mathcal{U}_d$ such that $f \simeq h$ in $\mathcal{U}_d$ and

$$h(a) = A_{g(a), 1, 1/2} \quad \text{for all } a \in K.$$ 

Using (4.5)(d), we may deform the loop at $t = \frac{1}{2}$ to attach $n$ eights to $h$ at $t = \frac{1}{2}$ (for arbitrary $n \geq 1$). Thus $h \simeq B_{h, n, 1/2}$. Together with (4.5)(e), this implies that $f \simeq B_{f, n, 1/2}$ within $\mathcal{U}_d$. \hfill \Box

(4.19) Theorem. Let $Q = (q, z) \in \mathbb{C} \times S^1$ and $\theta_1 \in \mathbb{R}$ satisfy $e^{i\theta_1} = z$. Then the subspace $\mathcal{U}_d \subset \mathcal{L}^+_1(Q; \theta_1)$ consisting of all diffuse curves is homeomorphic to $E$, and hence contractible.

Proof. Because $\mathcal{U}_d$ is open, it suffices to prove that it is weakly contractible, by (1.7)(b). Let $k \in \mathbb{N}$, $f : S^k \to \mathcal{U}_d$ be continuous and $g : S^k \to \mathcal{U}_d$ be a map satisfying (i)–(iii) of (1.11) (with $\mathcal{U} = \mathcal{U}_d$). By (4.1), there exists $G : [0, 1] \times S^k \to \mathbb{C}^+\infty(Q)$ such that $G_0 = g$ and $G_1$ is a constant map. By (4.6), there exists $n_0 \in \mathbb{N}$ such that if $n \geq n_0$, then $S_{G(s, a, n)} \in \mathcal{U}_d$ for all $s \in [0, 1]$, $a \in S^k$. Applying (4.18) and (4.7) to $g$, we obtain $n_1 \geq n_0$ and a continuous $F : [-1, 0] \times S^k \to \mathcal{U}_d$ with $F_{-1} = g$ and $F_0 = S_{g, n_1}$. Concatenating $F$ and $S_{G, n_1}$ we obtain a null-homotopy of $g$ in $\mathcal{U}_d$. \hfill \Box

5. Critical curves

Fix $Q = (q, z) \in \mathbb{C} \times S^1$ and $\theta_1 \in \mathbb{R}$ satisfying $e^{i\theta_1} = z$. Let $\gamma \in \mathcal{L}^+_1(Q; \theta_1)$ and $\theta : [0, 1) \to \mathbb{R}$ be the argument of $t_\gamma$ satisfying $\theta(0) = 0$. Finally, let

$$\theta^+ = \sup_{t \in [0, 1]} \theta(t) \quad \text{and} \quad \theta^- = \inf_{t \in [0, 1]} \theta(t).$$

Recall that $\gamma$ is called critical if $\theta^+ - \theta^- = \pi$. A curve $\eta \in \mathcal{L}^+_1(Q; \theta_1)$ must be either condensed, diffuse or critical. It has already been shown that the subspace $\mathcal{U}_c$ (resp. $\mathcal{U}_d$) of $\mathcal{L}^+_1(Q; \theta_1)$ consisting of all condensed (resp. diffuse) curves is contractible. Let $\mathcal{T} \subset \mathcal{L}^+_1(Q; \theta_1)$ denote the subspace of all critical curves. Clearly, $\mathcal{T}$ is closed as the complement of $\mathcal{U}_c \cup \mathcal{U}_d$. Since the difference $\theta^+ - \theta^-$ depends continuously on $\gamma$, we deduce that $\partial \mathcal{U}_c \subset \mathcal{T}$ and $\partial \mathcal{U}_d \subset \mathcal{T}$, where $\partial \mathcal{U}_c$ denotes the topological boundary of $\mathcal{U}_c$ considered as a subspace of $\mathcal{L}^+_1(Q; \theta_1)$ and similarly for $\mathcal{U}_d$.

(5.1) Proposition. Let $|\theta_1| < \pi$ and $\mathcal{U}_c, \mathcal{U}_d, \mathcal{T} \subset \mathcal{L}^+_1(Q; \theta_1)$ be as above. Then $\partial \mathcal{U}_c = \partial \mathcal{U}_d = \mathcal{T}$. Therefore, $\mathcal{U}_c \cup \mathcal{U}_d = \mathcal{L}^+_1(Q; \theta_1)$ and $\mathcal{U}_c \cap \mathcal{U}_d = \mathcal{T}$.

Observe that $\mathcal{T} = \emptyset$ if $|\theta_1| > \pi$ and $\mathcal{U}_c = \emptyset$ if $|\theta_1| \geq \pi$. However, in any case $\partial \mathcal{U}_d = \mathcal{T}$.

Proof. Let $\gamma \in \mathcal{L}^+_1(Q; \theta_1)$ be a critical curve and $\mathcal{V} \subset \mathcal{L}^+_1(Q; \theta_1)$ be an open set containing $\gamma$. Let $\theta$ be the argument of $t_\gamma$ satisfying $\theta(0) = 0$, and let $\theta^+, \theta^-$ be as in (40).
We first prove that $\mathcal{V} \cap \mathcal{U}_c \neq \emptyset$. Our immediate objective is to replace $\gamma$ with another curve in $\mathcal{V} \cap \mathcal{T}$ having smaller curvature. Choose $t_1 \in (0, 1)$ and $\delta > 0$ such that $\theta(t) \in (\theta^-, \theta^+)$ for all $t \in [t_1 - \delta, t_1]$. Let $Q_0 = \Phi_\gamma(t_1 - \delta)$, $Q_1 = \Phi_\gamma(t_1)$ and consider the map

$$F : \mathcal{L}^{+1}_1(Q_0, \cdot) \to UTC, \quad F(\eta) = \Phi_\eta(1).$$

(Recall that $\mathcal{L}^{+1}_1(Q_0, \cdot)$ consists of all $(-1, 1)$-admissible curves having initial frame equal to $Q_0$ and arbitrary final frame.) By (1.5), $F$ is an open map. It follows that for any $\tilde{Q}_1$ close enough to $Q_1$, we can find $\eta \in \mathcal{L}^{+1}_1(Q_0, \tilde{Q}_1)$ such that

$$\theta_\eta([0, 1]) \subset (\theta^-, \theta^+).$$

Let $Q_1 = (q_1, z_1)$ and $Q = (q, z)$. Since $\gamma$ is critical, the image of $t_\gamma$ is contained in a semicircle. Consequently, $q \neq 0$. Choose $\kappa_0 \in (0, 1)$ close to 1. Replace the arc $\gamma|_{[t_1 - \delta, t_1]}$ by a curve $\eta$ as above with $\tilde{Q}_1 = (q_1 + (\kappa_0 - 1)q, z_1)$, and the arc $\gamma|_{[t_1, 1]}$ by its translate $\gamma|_{[t_1, 1]} + (\kappa_0 - 1)q$. Let $\gamma_1$ be the resulting curve; observe that $\gamma_1$ is critical, $\Phi_{\gamma_1}(0) = (0, 1)$ and $\Phi_{\gamma_1}(1) = (\kappa_0 q, z)$. Set $\gamma_2 = (1/\kappa_0)\gamma_1$ (that is, $\gamma_2(t)$ is obtained from $\gamma_1(t)$ by a dilatation through a factor of $1/\kappa_0$ for all $t \in [0, 1]$). Then

$$\Phi_{\gamma_2}(0) = (0, 1), \quad \Phi_{\gamma_2}(1) = (q, z),
\begin{align*}
t_{\gamma_2}(t) &= t_{\gamma_1}(t), \quad \kappa_{\gamma_2}(t) = \kappa_0\kappa_{\gamma_1}(t) \quad \text{for all } t \in [0, 1].
\end{align*}$$

Thus, $\gamma_2$ is a critical curve in $\mathcal{L}^{+1}_1(Q; \theta_1)$ whose curvature is constrained to $(-\kappa_0, \kappa_0)$. Moreover, if $\kappa_0$ is close enough to 1 and $\eta$ is chosen appropriately, we can guarantee that $\gamma_2 \in \mathcal{V}$.

Having established the existence of $\gamma_2$ with these properties, let us return to the beginning, setting $\gamma = \gamma_2 \in \mathcal{V}$. Since $|\theta_1| < \pi$, either

$$\theta^{-1}((\theta^-)) \cap \{0, 1\} = \emptyset \quad \text{or} \quad \theta^{-1}((\theta^+)) \cap \{0, 1\} = \emptyset,$$

and we lose no generality in assuming the latter. Choose $\varepsilon > 0$ small enough to guarantee that

$$W = \theta^{-1}((\theta^+ - \varepsilon, \theta^+)) \subset (0, 1).$$

Cover $\theta^{-1}((\theta^+))$ by the finite union of disjoint intervals $(a_i, b_i) \subset W$ with $\theta(a_i) = \theta(b_i) = \theta^+ - \varepsilon$, $i = 1, \ldots, m$. Let $P_i = \Phi_\gamma(a_i)$, $Q_i = \Phi_\gamma(b_i)$. We can obtain a curve in $\mathcal{U}_c \cap \mathcal{V}$ by modifying $\gamma$ in each of these intervals to avoid the argument $\theta^+$ using (3.4): note that $P_i^{-1} \gamma|_{[a_i, b_i]}$ satisfies the hypotheses of (3.16) because it has curvature in the open interval $(-\kappa_0, +\kappa_0)$ and is not a line segment. Moreover, the inclusion $\hat{\mathcal{L}}_{-\kappa_0}^{+\kappa_0}(P_i^{-1} Q_i) \to \mathcal{L}^{+1}_{-\kappa_0}(P_i^{-1} Q_i)$ is continuous by (1.17).

The proof that $\mathcal{V} \cap \mathcal{U}_d \neq \emptyset$ is easier. Let the critical curve $\gamma : [0, L] \to \mathbb{C}$ be parametrized by arc-length. Then we can find $s_0, s_1 \in [0, 1]$ with $t_\gamma(s_0) = -t_\gamma(s_1)$. 
Choose $\varepsilon > 0$ and let 

$$G_\gamma = G_{\gamma, (s_0, s_1), (\varepsilon, \varepsilon)}.$$ 

(See (4.13) and Figure 8.) Choose $\kappa_0 \in (0, 1)$ and construct a curve $\zeta \in \mathcal{L}_{-1}^{+1}(Q; \theta_1)$ by replacing the line segment $G_\gamma|_{[s_0, s_0+\varepsilon]}$ by three small arcs of circles of radius $1/\kappa_0$ as indicated below:

If the bump is chosen to lie on the correct side, the curve $\zeta$ will be diffuse, and if $\varepsilon > 0$ is small enough, then $\zeta \in \mathcal{V}$. (Notice that this part of the proof works even if $|\theta_1| = \pi$.)

We have established that $T \subset \partial\mathcal{U}_d \cap \partial\mathcal{U}_c$. As explained at the beginning of the section, $\partial\mathcal{U}_c \subset T$ and $\partial\mathcal{U}_d \subset T$. Thus, $\partial\mathcal{U}_c = \partial\mathcal{U}_d = T$. □

Existence of critical curves. It is immediate from the definition of “critical curve” that if $|\theta_1| > \pi$, then the subspace $T \subset \mathcal{L}_{-1}^{+1}(Q; \theta_1)$ must be empty. In this subsection we shall determine exactly when $T = \emptyset$ for $|\theta_1| \leq \pi$.

(5.2) Definition. A sign string $\sigma$ is an alternating finite sequence of signs, such as $+-+-$ or $-++-$. As part of the definition we require that its length $|\sigma|$, the number of terms in the string, satisfy $|\sigma| \geq 2$. Let $\sigma(k)$ denote its $k$-th term ($1 \leq k \leq |\sigma|$). The opposite $-\sigma$ of $\sigma$ is the unique sign string satisfying $|-\sigma| = |\sigma|$ and $(-\sigma)(k) = -\sigma(k)$.

A critical curve $\gamma : [0, 1] \to \mathbb{C}$ is of type $\sigma$ if there exist $0 \leq t_1 < t_2 < \cdots < t_{|\sigma|} \leq 1$ with $\theta(t_k) = \theta_{\sigma(k)}$ (recall that $\theta^+ = \sup_{t \in [0, 1]} \theta(t)$ and $\theta^- = \inf_{t \in [0, 1]} \theta(t)$, where $e^{i\theta} = t_\gamma$), but it is impossible to find $0 \leq s_1 < \cdots < s_{|\sigma|+1} \leq 1$ such that $t_\gamma(s_k) = -t_\gamma(s_{k+1})$ for each $k = 1, \ldots, |\sigma|$. 

Given a sign string $\sigma$, one can determine whether there exist critical curves of type $\sigma$ in $\mathcal{L}_{-1}^{+1}(Q; \theta_1)$ using an elementary geometric construction; see Figure 9.

(5.3) Proposition. Let $\theta_1 \in [0, \pi]$, $z = e^{i\theta_1}$ and $Q = (q, z) \in \mathbb{C} \times S^1$. Let $\sigma$ be a sign string,

$$a = i\sigma(1)(1 + (-1)^{|\sigma|+1}z) \in \mathbb{C} \quad \text{and} \quad r = 2|\sigma| \in \mathbb{N}.$$ 

Let $R_\sigma$ be the open region of the plane which does not contain $-i + iz$ and which is bounded by the shortest arc of $C_r(a)$ joining $a + ri$ to $a - ri$ and the tangent lines to $C_r(a)$ at these points. Then $\mathcal{L}_{-1}^{+1}(Q; \theta_1)$ contains critical curves of type $\sigma$ if and only if $q \in R_\sigma$. 
We have assumed that $\theta_1 \in [0, \pi]$ just to simplify the statement. If $\theta_1 \in [-\pi, 0]$, then the only differences are that the points bounding the arc of $C_r(a)$ are now $a - ri$ and $a + riz$ and the region $R_\sigma$ is the one not containing $i - iz$. Indeed, reflection across the $x$-axis yields a homeomorphism between $L_{-1}^+(\bar{Q}; \theta_1)$ and $L_{-1}^+(\bar{Q}; -\theta_1)$, where $Q = (\bar{q}, \bar{z})$, which maps critical curves of type $\sigma$ to critical curves of type $-\sigma$.

When $\theta_1 = 0$, the points $a + ri$ and $a - ri$ determine two shortest arcs of $C_r(a)$, not just one; the region $R_\sigma$ is bounded by the one which goes through $a + r$. When $\theta_1 = \pm\pi$, the arc of circle degenerates to a single point. In this case, $R_\sigma$ is the

Figure 9. The regions $R_\sigma$ of (5.3).
component of the complement of the horizontal line through \( a + \text{sign}(\theta_1)ri \) which does not contain the real axis.

**Proof of (5.3).** There are four essentially distinct types of sign strings to consider:

\[
\underbrace{+\cdots+}_{2n}, \quad \underbrace{-\cdots-}_{2n}, \quad \underbrace{+\cdots-}_{2n} \quad \text{and} \quad \underbrace{-\cdots+}_{2n} \quad (n \in \mathbb{N}, n \geq 1).
\]

(Note that these are distinguished by the values of \( \sigma \) (1) and \( |\sigma| \) appearing in the expression for \( a \).) We shall prove the theorem for a string of the first type; the proof in the remaining three cases is analogous. The argument given here is the same as the one which was used to prove (3.17), so some details will be omitted.

For each \( \mu \in [\theta_1 - \pi, 0] \), let \( \gamma_\mu : [0, 2n\pi + \theta_1] \to \mathbb{C} \) be the unique curve parametrized by arc-length satisfying

\[
\gamma_\mu(0) = 0, \quad t_{\gamma_\mu}(s) = \begin{cases} e^{is} & \text{if } s \in [0, \mu + \pi] \cup [\mu + 2n\pi, \theta_1 + 2n\pi] \cup_k [\mu + k\pi, \mu + (k+1)\pi], \\ e^{i(2\mu - s)} & \text{if } s \in \bigcup_k [\mu + k\pi, \mu + (k+1)\pi], \end{cases}
\]

where the first (resp. second) union is over all \( k \equiv 0 \) (resp. \( k \equiv 1 \) (mod 2), \( 1 \leq k \leq 2n - 1 \). Notice that \( \gamma_\mu \) is the concatenation of arcs of circles of radius 1; see Figure 9. (Vaguely speaking, \( \gamma_\mu \) is the “most efficient” critical curve \( \gamma \) of type \( \sigma \) with \( \inf \theta_\gamma = \mu \) and \( |\kappa_\gamma| \leq 1 \).) We have

\[
\Phi_{\gamma_\mu}(0) = (0, 1), \quad t_{\gamma_\mu}(2n\pi + \theta_1) = z, \quad \inf \theta_{\gamma_\mu} = \mu, \quad \sup \theta_{\gamma_\mu} = \mu + \pi,
\]

\[
\gamma_\mu(2n\pi + \theta_1) = \left( \int_0^{\mu + \pi} + (2n - 1) \int_\mu^{\mu + \pi} + \int_\mu^{\theta_1} \right) e^{is} ds = (i - iz) + 4ni e^{i\mu}.
\]

From the previous equation it follows that as \( \mu \) increases from \( \theta_1 - \pi \) to 0, the endpoint of \( \gamma_\mu \) traces out the arc of \( C_r(a) \) joining \( a - ri z \) to \( a + ri \), where \( a = i - iz \) and \( r = 4n = 2|\sigma| \). Further, the tangent line to \( C_r(a) \) at \( \gamma_\mu(2n\pi + \theta_1) \) is parallel to \( e^{i\mu} \), for it must be orthogonal to \( 4ni e^{i\mu} \).

It is easy to see that any \( q \in \tilde{R}_\sigma \) is the endpoint of a curve of one of the following three types:

(i) The concatenation of \( \gamma_\mu \) with a line segment of direction \( z \) for some \( \mu \in [\theta_1 - \pi, 0] \).

(ii) The concatenation of \( \gamma_0[[0,\pi]] \), a line segment of length \( \ell \geq 0 \) having direction \(-1\), the arc \(-\ell + \gamma_0[[\pi, 2n\pi + \theta_1]] \), and a line segment of direction \( z \).

(iii) The concatenation of \( \gamma_{\theta_1 - \pi}[[0,\theta_1 + \pi]] \), a line segment of length \( \ell_1 \geq 0 \) of direction \(-z\), the arc \(-\ell_1z + \gamma_0[[\theta_1 + \pi, \theta_1 + 3\pi/2]] \), a line segment of length \( \ell_2 \geq 0 \) and direction \(-iz\), the arc \(-\ell_1z - \ell_2iz + \gamma_0[[\theta_1 + 3\pi/2, 2n\pi + \theta_1]] \), and a line segment of direction \( z \).
If \( q \in R_\sigma \), then we can find a critical curve \( \gamma \) of type \( \sigma \) in \( \mathcal{L}^{+1}_{-1}(Q; \theta_1) \) by a slight modification of one of these curves.

Conversely, suppose that \( \mathcal{L}^{+1}_{-1}(Q; \theta_1) \) contains critical curves of type \( \sigma \). Let \( \eta : [0, L] \to \mathbb{C} \) be such a curve, parametrized by arc-length, and let \( \mu = \inf \theta \), where \( \theta : [0, L] \to \mathbb{R} \) is the argument of \( t_\eta \) satisfying \( \theta(0) = 0 \). Define

\[
g : [0, L] \to \mathbb{R} \quad \text{by} \quad g(s) = \langle \eta(s) - \gamma(2n\pi + \theta_1), i e^{i\mu}\rangle.
\]

Note that \( g(s) > 0 \) if and only if \( \eta(s) \) lies to the left of the line through \( \gamma(2n\pi + \theta_1) \in C_r(a) \) having direction \( e^{i\mu} \); we have already seen that this line is tangent to \( C_r(a) \) at this point. We claim that \( g(L) > 0 \). Since \( \eta \) is critical, \( \theta(s) \in [\mu, \mu + \pi] \) for all \( s \). Hence,

\[
g'(s) = \langle e^{i\theta(s)}, i e^{i\mu}\rangle = \cos(\theta(s) - (\mu + \frac{\pi}{2})) \geq 0 \quad \text{for all } s \in [0, L].
\]

Let \( J_i = (a_i, b_i) \subset (0, L), i = 0, \ldots, 2n = |\sigma| \), be disjoint intervals such that

(I) \( \theta(a_0) = 0 \) and \( \theta(b_1) = \mu + \pi \);

(II) \( \theta(a_i) = \mu + \pi \) and \( \theta(b_i) = \mu \) for \( i = 1, 3, \ldots, 2n - 1 \);

(III) \( \theta(a_i) = \mu \) and \( \theta(b_i) = \mu + \pi \) for \( i = 2, 4, \ldots, 2n - 2 \);

(IV) \( \theta(a_{2n}) = \mu + \pi \) and \( \theta(b_{2n}) = \theta_1 \).

Such intervals exist because \( \theta([0, L]) \subset [\mu, \mu + \pi] \), \( \theta(0) = 0 \), \( \theta(L) = \theta_1 \) and \( \eta \) is critical of type \( \sigma \). It follows from (42) and the fact \( \theta \) is strictly 1-Lipschitz (by (5) and the fact that \( \theta = \arg \circ t_\eta \) is absolutely continuous) that

\[
g(L) - g(0) \geq \left( \sum_{i=0}^{2n} \int_{a_i}^{b_i} \right) g'(s) ds
\]

\[
> \left( \int_0^{\mu+\pi} + (2n-1) \int_\mu^{\mu+\pi} + \int_{\mu}^{\theta_1} \right) \langle e^{i\theta}, i e^{i\mu}\rangle dt = \langle \gamma(2n\pi + \theta_1), i e^{i\mu}\rangle.
\]

Therefore, \( g(L) > 0 \) as claimed. We conclude that \( q = \eta(L) \) lies on the side of a tangent to \( C_r(a) \) which only contains points of \( R_\sigma \).

\( \square \)

(5.4) Corollary. Let \( Q = (q, z) \in \mathbb{C} \times \mathbb{S}^1 \),

\[
a = \text{sign}(\text{Im}(z))i(z - 1) \in \mathbb{C},
\]

and let \( R_T \) be the open region of the plane which does not contain \( a \) and which is bounded by the shortest arc of \( C_4(a) \) joining \( a + \text{sign}(\text{Im}(z))4i \) to \( a - \text{sign}(\text{Im}(z))4iz \) and the tangent lines to \( C_4(a) \) at these points. Then \( \mathcal{L}^{+1}_{-1}(Q) \) contains critical curves if and only if \( q \in R_T \).

\( \square \)

Proof. Let \( z = e^{i\theta_1}, |\theta_1| \leq \pi \). For \( \theta_1 \in [0, \pi) \) (resp. \( \theta_1 \in [-\pi, 0] \)), \( R_T \) is the same as the region \( R_{-+} \) (resp. \( R_{+-} \) ) appearing in (5.3).
If \( z = \pm 1 \), then \( \text{sign}(\text{Im } z) \) is not defined. When \( z = 1 \), \( R_\gamma \) is bounded by the semicircle centered at 0 through 4 and \( \pm 4i \) and the tangents to \( C_4(0) \) at the latter two points. When \( z = -1 \), \( R_\gamma \) is bounded by the horizontal lines through \( \pm 2i \).

(5.5) Corollary. Let \( Q = (q, z) \in \mathbb{C} \times \mathbb{S}^1 \) and \( e^{i\theta_1} = z \). Then there exist condensed curves but not critical curves in \( \mathcal{L}^+_{-1}(Q; \theta_1) \) if and only if \( |\theta_1| < \pi \) and \( q \) lies in the region illustrated in Figure 1.

Proof. This is an immediate consequence of (3.17) and (5.4).

(5.6) Lemma. Let \( Q = (q, z) \in \mathbb{C} \times \mathbb{S}^1 \) and \( e^{i\theta_1} = z \). Let \( \omega \in \{0, \pi\} \) and \( r(\omega) = 4 \sin(\omega/2) \). Suppose that \( q \) lies inside of \( C_r(\omega) \) \( (\text{sign}(\theta_1)i(z-1)) \). Then there does not exist a curve in \( \hat{\mathcal{L}}^+_{-1}(Q; \theta_1) \) or \( \mathcal{L}^+_{-1}(Q; \theta_1) \) having amplitude \( \omega \).

Proof. Assume that \( \theta_1 \in [0, \pi] \); the proof for \( \theta_1 \in [-\pi, 0] \) is analogous. Let \( \omega \in [\theta_1, \pi], \mu \in [\theta_1 - \omega, 0] \) and let \( \gamma_\mu : [0, 2\omega - \theta_1] \to \mathbb{C} \) be the unique curve parametrized by arc-length satisfying

\[
\gamma_\mu(0) = 0 \quad \text{and} \quad t_{\gamma_\mu}(s) = \begin{cases} e^{-is} & \text{if } s \in [0, -\mu], \\
 e^{i(s+2\mu)} & \text{if } s \in [-\mu, -\mu + \omega], \\
 e^{-i(s-2\omega)} & \text{if } s \in [-\mu + \omega, 2\omega - \theta_1].
\end{cases}
\]

Notice that \( t_{\gamma_\mu}(0) = 1, t_{\gamma_\mu}(2\omega - \theta_1) = z \) and \( \gamma_\mu \) is a concatenation of three arcs of circles of radius 1. Moreover, \( \inf_{t_{\gamma_\mu}} = \mu \) and \( \sup_{t_{\gamma_\mu}} = \mu + \omega \), where \( t_{\gamma_\mu} \) is the argument of \( t_{\gamma_\mu} \) satisfying \( \theta_{\gamma_\mu}(0) = 0 \). Consequently, \( \gamma_\mu \) has amplitude \( \omega \). Further,

\[
\gamma_\mu(2\omega - \theta_1) = \left( \int_{\mu}^{\mu + \omega} + \int_{\theta_1}^{\mu + \omega} \right) e^{is} ds = (-i + iz) + 4 \sin\left(\frac{\omega}{2}\right) e^{i(\mu + \omega/2)}.
\]

Thus, as \( \mu \) increases from \( \theta_1 - \omega \) to 0, the endpoint of \( \gamma_\mu \) traverses an arc of \( C_r(\omega)(-i + iz) \). Suppose that there exists \( \eta \in \hat{\mathcal{L}}^+_{-1}(Q; \theta_1) \) of amplitude \( \omega \), and let \( \eta : [0, L] \to \mathbb{C} \) be parametrized by arc-length. Let \( \theta_\eta \) be the argument of \( \eta \) satisfying \( \theta_\eta(0) = 0 \), take \( \mu = \inf \theta_\eta \) and define

\[
g : [0, L] \to \mathbb{R} \quad \text{by} \quad g(s) = \left( \eta(s) - \gamma_\mu(2\omega - \theta_1), e^{i(\mu + \omega/2)} \right).
\]

Then the same reasoning used to establish (3.17) and (5.3) shows that \( g(L) \geq 0 \). This implies that \( \eta(L) = q \) lies on or to the left of the line through \( \gamma_\mu(2\omega - \theta_1) \) having direction \( \exp\left(i(\mu + (\omega - \pi)/2)\right) \). This line is tangent to \( C_r(\omega)(-i + iz) \) at this point; therefore \( q \) cannot lie inside of this circle. This proves the assertion about \( \hat{\mathcal{L}}^+_{-1}(Q; \theta_1) \). Since the latter contains \( \mathcal{L}^+_{-1}(Q; \theta_1) \) as a subset, the proof is complete.

The next result will only be needed in [Saldanha and Zühlke 2015]. Recall the definition of \( \bar{\varphi}_\gamma \) in (34).
(5.7) Corollary. Let $|\theta_1| \leq \pi$, $e^{i\theta_1} = z$, $Q = (q, z) \in \mathbb{C} \times S^1$ and $\sigma$ be a sign string. Then the set of all $\varphi \in \mathbb{R}$ such that there exists a critical curve $\gamma \in \mathcal{L}^+_{-1}(Q; \theta_1)$ of type $\sigma$ for which $\bar{\varphi}_\gamma = \varphi$ is an open interval.

Proof. No generality is lost in assuming that $\theta_1 \in [0, \pi)$. Let $\varphi \in \mathbb{R}$. It was established in the proof of (5.3) that a curve $\gamma$ as in the statement exists if and only if $\varphi \in [\theta_1 - \pi/2, \pi/2]$ and $q$ lies in the open external region $E_\varphi$ determined by the tangent orthogonal to $\phi^{i\varphi}$ to a certain circle $C$ (which depends only on $\theta_1$ and $\sigma$). It is straightforward to check that $E_{\varphi_1} \cap E_{\varphi_2} \subset E_\varphi$ whenever $\varphi \in [\varphi_1, \varphi_2]$ with $\varphi_2 - \varphi_1 \leq \pi$. Moreover, if $q \in E_\varphi$, then $q \in E_\bar{\varphi}$ for all $\bar{\varphi}$ sufficiently close to $\varphi$. □

6. Components of $\mathcal{L}_{\kappa_1}^{\pm_2}(P, Q)$ for $\kappa_1\kappa_2 < 0$

Recall that $E$ denotes the separable Hilbert space and $B_{\gamma,1,1/2}$ is obtained from $\gamma$ by attaching a figure eight curve (at $t = 1/2$); see (4.4) and Figure 7(d).

(6.1) Theorem. Let $Q = (q, z) \in \mathbb{C} \times S^1$ and $\theta_1 \in \mathbb{R}$ satisfy $e^{i\theta_1} = z$. Then the following assertions are equivalent:

(i) $\mathcal{L}^+_{-1}(Q; \theta_1)$ is disconnected.

(ii) $|\theta_1| < \pi$ and $q$ lies in the region depicted in Figure 1.

(iii) $|\theta_1| < \pi$ and there exist condensed curves, but not critical curves, in $\mathcal{L}^+_{-1}(Q)$.

(iv) $|\theta_1| < \pi$ and there exist condensed curves in $\mathcal{L}^+_{-1}(Q)$, but no condensed curve is homotopic to a diffuse curve within $\mathcal{L}^+_{-1}(Q)$.

(v) $|\theta_1| < \pi$ and there exists an embedding $\gamma \in \mathcal{L}^+_{-1}(Q)$ which cannot be homotoped within this space to create self-intersections.

(vi) $|\theta_1| < \pi$ and there exists $\gamma \in \mathcal{L}^+_{-1}(Q)$ which does not lie in the same component as $B_{\gamma,1,1/2}$.

Furthermore, if $\mathcal{L}^+_{-1}(Q; \theta_1)$ is disconnected, then it has exactly two components; one of them is $U_c$ and the other is $U_d \subset \mathcal{L}^+_{-1}(Q; \theta_1)$, and both are homeomorphic to $E$, and hence contractible.

Proof. We know from (3.3) and (4.19) that each of $U_c$, $U_d \subset \mathcal{L}^+_{-1}(Q; \theta_1)$ is homeomorphic to $E$, and hence connected. By (4.10), $U_d \neq \emptyset$. By (5.1), $\bar{U}_c \cup \bar{U}_d = \mathcal{L}^+_{-1}(Q; \theta_1)$, and $\bar{U}_c \cap \bar{U}_d$ consists of all the critical curves in $\mathcal{L}^+_{-1}(Q; \theta_1)$. Thus, the latter has at most two connected components. It has exactly two if and only if $\bar{U}_c \neq \emptyset$ but $\bar{U}_c \cap \bar{U}_d = \emptyset$, that is, if and only if there exist condensed curves, but not critical curves. This proves the last assertion of the theorem and also the equivalence (i)$\Leftrightarrow$(iii). The equivalence (ii)$\Leftrightarrow$(iii) was proved in (5.5).

Suppose that $s \mapsto \gamma_s \in \mathcal{L}^+_{-1}(Q; \theta_1)$ is a path joining a condensed curve to a diffuse curve. Let $\theta_s$ be the argument of $t_{\gamma_s}$ satisfying $\theta_s(0) = 0$. By continuity,
there must exist $s_0 \in (0, 1)$ such that
\[
\sup_{t \in [0, 1]} \theta_{s_0}(t) - \inf_{t \in [0, 1]} \theta_{s_0}(t) = \pi;
\]
that is, there must exist $s_0$ such that $\gamma_{s_0}$ is critical. Hence, (iii)$\Rightarrow$(iv).

Suppose that (iv) holds, and let $\gamma \in \mathcal{L}^+_1(Q)$ be smooth and condensed. Then $\gamma$ is an embedding, but it cannot be deformed to have a self-intersection since any curve with double points must be diffuse. Thus, (iv)$\Rightarrow$(v).

Finally, it is obvious that (v)$\Rightarrow$(vi) and (vi)$\Rightarrow$(i).

(6.2) Corollary. Let $Q = (q, z) \in \mathbb{C} \times S^1$ and $\theta_1 \in \mathbb{R}$ satisfy $e^{i\theta_1} = z$. If $|\theta_1| \geq \pi$, then $\mathcal{L}^+_1(Q; \theta_1)$ is connected. If $|\theta_1| > \pi$, then $\mathcal{L}^+_1(Q; \theta_1)$ is homeomorphic to $E$, and hence contractible.

Proof. The first assertion is an immediate consequence of (6.1). If $|\theta_1| > \pi$ then $\mathcal{L}^+_1(Q; \theta_1)$ can only contain diffuse curves, and we know from (4.19) that $U_d$ is homeomorphic to $E$. □

Remark. The results of Section 4 go through to show that $\mathcal{L}^+_1(Q; \theta_1) = \mathcal{T} \cup U_d$ is also contractible when $\theta_1 = \pm \pi$. Of course, if $|\theta_1| < \pi$ then $\mathcal{L}^+_1(Q; \theta_1)$ need not even be connected. We shall prove in the sequel [Saldanha and Zühlke 2015] that it may also be contractible, or connected but not contractible, depending on $Q$.

(6.3) Corollary. Let $Q = (q, z) \in \mathbb{C} \times S^1$ and $\theta_1 \in \mathbb{R}$ satisfy $e^{i\theta_1} = z$. Then the subset $\mathcal{L}^+_1(Q; \theta_1)$ is either a connected component or the union of two contractible components of $\mathcal{L}^+_1(Q)$. The latter can occur only if $|\theta_1| < \pi$, that is, for at most one value of $\theta_1$.

(6.4) Theorem. Let $P = (p, w), Q = (q, z) \in \mathbb{C} \times S^1, \kappa_1 < 0 < \kappa_2$ and let $\theta_1$ satisfy $e^{i\theta_1} = z \bar{w}$.

(a) If $|\theta_1| \geq \pi$, then the subspace $\mathcal{L}^+_{\kappa_1}(P, Q; \theta_1)$ consisting of all curves having total turning $\theta_1$ is a contractible connected component of $\mathcal{L}^+_{\kappa_1}(P, Q)$, homeomorphic to $E$.

(b) If $|\theta_1| < \pi$, then $\mathcal{L}^+_{\kappa_1}(P, Q; \theta_1)$ has at most two components. It is disconnected if and only if any of the conditions in (6.1) are satisfied for $\hat{Q} = (\hat{q}, z \bar{w})$, where
\[
\hat{q} = \frac{2}{\rho_2 - \rho_1} \bar{w} \left( (q - p) + \frac{i}{2} (\rho_1 + \rho_2) (z - w) \right), \quad \rho_i = \frac{1}{\kappa_i}, i = 1, 2.
\]

In this case, one component consists of all condensed and the other of all diffuse curves in $\mathcal{L}^+_{\kappa_1}(P, Q; \theta_1)$, and both are homeomorphic to $E$.

Proof. This is just a corollary of (2.4)(a), (6.1) and (6.2).

We emphasize that the subspace of $\mathcal{L}^+_{\kappa_1}(P, Q)$ which contains curves having least total turning, described in (b), does not have to be contractible even if it is connected. Observe also that we may replace $\mathcal{L}$ by $\mathcal{C}$ invoking (1.12).
7. Homeomorphism class of $\mathcal{L}_{k_1}^{k_2}(P, Q)$ for $k_1 k_2 \geq 0$

An admissible plane curve $\gamma$ is called locally convex if either $k_1 \gamma > 0$ a.e. or $k_\gamma < 0$ a.e. Notice that $\mathcal{L}_{k_1}^{k_2}(P, Q)$ consists of locally convex curves if and only if $k_1 k_2 \geq 0$. This corresponds to parts (b)–(e) of (2.4). The topology of these spaces is very simple.

Suppose that $\gamma : [0, 1] \to \mathbb{C}$ is an admissible curve such that $k_\gamma > 0$ a.e. and $\Phi_\gamma(0) = (0, 1)$. By (5), any argument $\theta : [0, 1] \to \mathbb{R}$ of $t_\gamma$ must be strictly increasing; in particular, the total turning $\theta_1$ of $\gamma$ is positive. Thus, $\gamma$ may be parametrized by its argument $\theta \in [0, \theta_1]$. By the chain rule,

$$\dot{\gamma}(\theta) = \rho(\theta)e^{i\theta} \quad (\theta \in [0, \theta_1]),$$

where $\rho : [0, \theta_1] \to (0, +\infty)$ is the radius of curvature of $\gamma$. 3

(7.1) Theorem. Let $P, Q \in UT\mathbb{C}$ and suppose that either $k_1 \geq 0$ or $k_2 \leq 0$. Then $\mathcal{L}_{k_1}^{k_2}(P, Q)$ has infinitely many connected components, one for each realizable total turning. All of these components are homeomorphic to $E$, and hence contractible.

Proof. Using an Euclidean motion if necessary, we may assume that $P = (0, 1)$. Further, by reversing the orientation of all curves, we pass from the case where $k_2 \leq 0$ to the case where $k_1 \geq 0$.

Let $Q = (q, z)$ and $e^{i\theta_1} = z$. The subspace $\mathcal{L}_{k_1}^{k_2}(Q; \theta_1)$ is both open and closed in $\mathcal{L}_{k_1}^{k_2}(Q)$ (but it may be empty; see (4.9). In particular, two curves which have different total turnings cannot lie in the same component of $\mathcal{L}_{k_1}^{k_2}(Q)$.

For any $k \in \mathbb{N}$, we may concatenate a curve in $\mathcal{L}_{k_1}^{k_2}(Q)$ with a circle of curvature in $(k_1, k_2)$ traversed $k$ times. This shows that the number of components is infinite.

Suppose that $\mathcal{L}_{k_1}^{k_2}(Q; \theta_1) \neq \emptyset$. Since $k_1 \geq 0$ by hypothesis, we may reparametrize all curves in $\mathcal{L}_{k_1}^{k_2}(Q; \theta_1)$ by the argument $\theta \in [0, \theta_1]$ of their unit tangent vectors using (1.15). Choose any $\gamma_0 \in \mathcal{L}_{k_1}^{k_2}(Q; \theta_1)$ and define a map $H$ on $[0, 1] \times \mathcal{L}_{k_1}^{k_2}(Q; \theta_1)$ by

$$H(s, \gamma) = \gamma_s, \quad \gamma_s(\theta) = (1 - s)\gamma_0(\theta) + s\gamma(\theta) \quad (s \in [0, 1], \theta \in [0, \theta_1]).$$

Then $\gamma_s(0) = 0$, $\gamma_s(\theta_1) = q$ and the unit tangent vector $t_{\gamma_s}$ to $\gamma_s$ satisfies

$$t_{\gamma_s}(\theta) = e^{i\theta} \quad \text{for all } \gamma \in \mathcal{L}_{k_1}^{k_2}(Q; \theta_1), \ s \in [0, 1] \text{ and } \theta \in [0, \theta_1].$$

Consequently, each $\gamma_s$ has total turning $\theta_1$, $\Phi_{\gamma_s}(0) = (0, 1)$ and $\Phi_{\gamma_s}(\theta_1) = Q$. Let $\rho_0, \rho : [0, 1] \to (0, +\infty)$ denote the radii of curvature of $\gamma_0, \gamma$, respectively. It follows from (43) that the radius of curvature $\rho_s$ of $\gamma_s$ is given by

$$\rho_s = (1 - s)\rho_0 + s\rho.$$

---

3The idea of parametrizing a locally convex curve by the argument of its unit tangent vector is not new. It appears in [Little 1970], where it is attributed to W. Pohl. We do not know whether it is older than that.
Therefore, the curvature $\kappa_s = 1/\rho_s$ of $\gamma_s$ takes values in $(\kappa_1, \kappa_2)$ and $H$ is a contraction of $\mathcal{L}_{\kappa_1^2}^k(Q; \theta_1)$. We conclude that the latter is a connected component of $\mathcal{L}_{\kappa_1^2}^k(Q)$ and, using (1.7)(b), that it is homeomorphic to $E$. \hfill \Box

Possible total turnings of a curve in $\mathcal{L}_{\kappa_1^2}^k(P, Q)$ when $\kappa_1 \kappa_2 > 0$. Let $T$ denote the set of all total turnings which are realized by some curve in $\mathcal{L}_{\kappa_1^2}^k(P, Q)$. If $P = (p, w), Q = (q, z)$, then obviously

$$T \subset \{ \theta_1 + 2k\pi : k \in \mathbb{Z} \}, \quad \text{where } e^{i\theta_1} = z\bar{w}.$$ 

If $\kappa_1 \kappa_2 < 0$, this inclusion is an equality by (4.9)(b). However, it must be proper when $\kappa_1 \kappa_2 \geq 0$. If $\kappa_1, \kappa_2$ are both positive, for instance, then, by (5) and the second paragraph of the above proof, $T$ must have the form $\{ \mu + 2k\pi : k \in \mathbb{N} \}$, where $\mu \in \mathbb{R}$ ($e^{i\mu} = z\bar{w}$) is the minimal attainable total turning in this space. It is possible to find the value of $\mu$ in terms of all parameters involved. Because this determination is of lesser interest and relatively technical, we shall not go into it here. However, interested readers can find the details, including the analogue for spaces of the form $\hat{\mathcal{L}}$, in [Saldanha and Zühlke 2014]. We mention only that (2.4) allows one to restrict attention to the two classes $\mathcal{L}_{+\infty, 1}^k(Q)$ and $\mathcal{L}_{0, +\infty}^k(Q)$.

8. Components of spaces of curves on complete flat surfaces

By a flat surface we mean a connected Riemannian 2-manifold whose Gaussian curvature is identically zero; it will not be necessary to assume that $S$ is a submanifold of some Euclidean space. The unit tangent $t = t_\gamma : [0, 1] \rightarrow UTS$ to a regular curve $\gamma : [0, 1] \rightarrow S$ is defined as before, $t = \dot{\gamma}/|\dot{\gamma}|$. If $S$ is orientable, the unit normal $n = n_\gamma : [0, 1] \rightarrow UTS$ to $\gamma$ is defined by the condition that $(t(t), n(t))$ should be a positively oriented orthonormal basis of $TS_{\gamma(t)}$ for each $t \in [0, 1]$. For $\gamma$ of class $C^2$, we can then define its curvature $\kappa_\gamma : [0, 1] \rightarrow \mathbb{R}$ by

$$\kappa_\gamma = \frac{1}{|\dot{\gamma}|} \left\langle \frac{D t}{d t}, n \right\rangle,$$

where $D$ denotes covariant differentiation (along $\gamma$).

If $S$ is nonorientable, we can still speak of the unsigned curvature $\kappa_\gamma : [0, 1] \rightarrow [0, +\infty)$ of a curve $\gamma : [0, 1] \rightarrow S$, given by

$$\kappa_\gamma = \frac{1}{|\dot{\gamma}|} \left| \left\langle \frac{D t}{d t}, n \right\rangle \right|,$$

where now $n(t)$ denotes any of the two unit vectors in $TS_{\gamma(t)}$ orthogonal to $t(t)$.

(8.1) Definition. Let $S$ be an orientable flat surface, $u, v \in UTS, -\infty \leq \kappa_1 < \kappa_2 \leq +\infty$, and $2 \leq r \in \mathbb{N}$. Define $\mathcal{C}S^k_{\kappa_1} (u, v)$ to be the set of all $C^r$ regular curves $\gamma : [0, 1] \rightarrow S$ satisfying
(i) \( t_\gamma(0) = u \) and \( t_\gamma(1) = v \);
(ii) \( \kappa_1 < \kappa_\gamma(t) < \kappa_2 \) for each \( t \in [0, 1] \).

In case \( S \) is nonorientable, define \( \mathcal{C}S^{-\kappa_0}_{-\kappa_0}(u, v) \) (\( \kappa_0 > 0 \)) as above, but replacing condition (ii) by

(ii') \( \kappa_\gamma(t) < \kappa_0 \) for each \( t \in [0, 1] \).

In both cases, let \( \mathcal{C}^{\kappa_2}_{\kappa_1}(u, v) \) be furnished with the \( C^r \) topology.

**Remark.** A complete flat surface must be homeomorphic to one of the following five: \( \mathbb{C} \) itself, a cylinder \( S^1 \times \mathbb{R} \), an open Möbius band, a torus or a Klein bottle. This is essentially a corollary of the following result; cf. [Hopf 1926, p. 319].

(8.2) **Theorem** (Killing–Hopf). Any complete flat surface is isometric to the quotient of the Euclidean plane \( \mathbb{C} \) by a group of isometries acting freely and properly discontinuously on \( \mathbb{C} \). □

Hence, if \( S \) is a complete flat surface, there exists a covering map \( \mathbb{C} \to S \) which is a local isometry. Any curve on \( S \) may thus be lifted to a plane curve whose curvature is the same as that of the original curve, with the proviso that we ignore its sign if \( S \) is nonorientable. Let \( \text{pr} : UT \mathbb{C} \to UTS \) denote the natural projection induced by the covering map. In what follows, when referring to \( \mathcal{C}S^{\kappa_2}_{\kappa_1}(u, v) \), we adopt the convention that \( \kappa_1 = -\kappa_2 < 0 \) if \( S \) is nonorientable.

(8.3) **Proposition.** Let \( S \) be a complete flat surface, \( u, v \in UTS \), \( -\infty \leq \kappa_1 < \kappa_2 \leq +\infty \) and \( P \in UT \mathbb{C} \) be a fixed element of \( \text{pr}^{-1}(u) \). Then \( \mathcal{C}S^{\kappa_2}_{\kappa_1}(u, v) \) is homeomorphic to \( \biguplus_{Q \in \text{pr}^{-1}(v)} \mathcal{C}^{\kappa_2}_{\kappa_1}(P, Q) \), where the homeomorphism maps a curve in the latter to its image under the quotient map \( \mathbb{C} \to S \). □

Here \( \biguplus \) denotes topological sum. Clearly, this decomposition is sufficient to determine the connected components of \( \mathcal{C}S^{\kappa_2}_{\kappa_1}(u, v) \) explicitly, using (1.12) and (6.4) if \( \kappa_1 \kappa_2 < 0 \) or (7.1) if \( \kappa_1 \kappa_2 \geq 0 \).

(8.4) **Corollary.** Let \( S \) be a complete flat surface, \( \kappa_1 < \kappa_2 \) and \( u, v \in UTS \). Then \( \mathcal{C}S^{\kappa_2}_{\kappa_1}(u, v) \) is nonempty and has an infinite number of connected components.

**Proof.** By (4.9) and the remark which follows it, \( \mathcal{C}^{\kappa_2}_{\kappa_1}(P, Q) \) is always nonempty. The assertion is thus an immediate consequence of (8.3). □

Notice that it is irrelevant here whether \( S \) is compact. This should be compared to the case of \( S = \mathbb{S}^2 \), where, at least when \( u = v \), the number of components of \( \mathcal{C}S^{\kappa_2}_{\kappa_1}(u, v) \) is finite for any choice of \( \kappa_1 < \kappa_2 \) (see [Saldanha and Zühlke 2013, §7]). This is actually not surprising, since the fundamental group of \( UT \mathbb{C} \) is isomorphic to \( \mathbb{Z} \), but that of \( UT \mathbb{S}^2 \cong SO_3 \) is isomorphic to \( \mathbb{Z}_2 \). We remark without proof that \( \mathcal{C}S^{\kappa_2}_{\kappa_1}(u, v) \) may be empty for more general surfaces (for instance, \( \mathcal{C}S^{+1}_{-1}(u, u) = \emptyset \) when \( S \) is the hyperbolic plane \( \mathbb{H}^2 \) for any \( u \in U \mathbb{H}^2 \)).
(8.5) Corollary. Let \( S \) be a complete flat surface and \( u, v \in UTS \). Let \( \eta \in \mathcal{C}S_{-\infty}^+(u, v) \) and suppose that \( \kappa_1 \kappa_2 < 0 \). Then there exists \( \gamma \in \mathcal{C}S_{\kappa_1}^+(u, v) \) lying in the same component of \( \mathcal{C}S_{-\infty}^+(u, v) \) as \( \eta \).

In other words, given a regular curve \( \eta \) on \( S \) with \( t_\eta(0) = u, t_\eta(1) = v \), we may deform \( \eta \) through regular curves, keeping \( t(0), t(1) \) fixed, to obtain a curve having curvature in \( (\kappa_1, \kappa_2) \) everywhere.

Proof. Take \( P \in UTC \) such that \( pr(P) = u \). Let \( \tilde{\eta} \) be the lift of \( \eta \) to \( \mathbb{C} \) with initial frame \( P \); let \( Q \) be its final frame and \( \theta_1 \) its total turning. By (4.9)(b), \( \mathcal{C}^\kappa_{\kappa_1}(P, Q; \theta_1) \) is nonempty. Let \( \tilde{\gamma} \) be one of its elements. Then the projection \( \gamma \) of \( \tilde{\gamma} \) on \( S \) satisfies the conclusion of the corollary because of (8.3) and the fact that \( \tilde{\eta}, \tilde{\gamma} \) lie in the same component of \( \mathcal{C}_{-\infty}^+(P, Q) \).

Again, the analogue of this result does not hold for a general surface \( S \), e.g., for \( S = \mathbb{H}^2 \). It is also false for a flat surface if \( \kappa_1 \kappa_2 > 0 \). To see this, let \( P, Q \in UTC \) satisfy \( pr(P) = u, pr(Q) = v \), choose \( \tilde{\eta} \in \mathcal{C}_{-\infty}^+(P, Q) \) to have a total turning which is unattainable for curves in \( \mathcal{C}^\kappa_{\kappa_1}(P, Q) \) and let \( \eta \) be the projection of \( \tilde{\eta} \) on \( S \).

9. Final remarks

Spaces of curves with curvature in a closed interval. Dubins [1957; 1961] worked with the set \( \hat{\mathcal{L}}_{-\kappa_0}^+(Q) \) of (1.16) (but with the \( C^1 \) topology), where the curvatures are restricted to lie in a closed interval. This choice is motivated by the fact that these spaces, unlike those of the form \( \mathcal{L}^+_{-\kappa_0}(Q) \), always contain curves of minimal length (see [Dubins 1957, Proposition 1]). All of the main results in our paper concerning the topology of \( \mathcal{L}_{\kappa_1}^+(P, Q) \) have analogues for \( \hat{\mathcal{L}}_{\kappa_1}^+(P, Q) \). We shall now briefly indicate the modifications which are necessary.

Notice that \( \hat{\mathcal{L}}_{\kappa_1}^+(P, Q) \) is not a Banach manifold, and that the analogue of (1.5) is false for these spaces, as shown by (1.1). In contrast, (1.14) and (1.15) still hold when \( M = \hat{\mathcal{L}}_{\kappa_1}^+(P, Q) \). The important corollary (2.6) has the following analogue, whose proof is essentially the same as that of (2.4); see (2.7).

(9.1) Proposition. Let \( P, Q \in UTC \) and \( \kappa_1 < \kappa_2 \) be finite. Then there exists a homeomorphism between \( \hat{\mathcal{L}}_{\kappa_1}^+(P, Q) \) and a space of type \( \hat{\mathcal{L}}_{-1}^{+1}(Q_0), \hat{\mathcal{L}}_{0}^{+1}(Q_0) \) or \( \hat{\mathcal{L}}_{1}^{+2}(Q_0) \), according to whether \( \kappa_1 \kappa_2 < 0, \kappa_1 \kappa_2 = 0 \) or \( \kappa_1 \kappa_2 > 0 \), respectively. Moreover, this homeomorphism preserves the total turning of curves unless \( \kappa_1 < \kappa_2 \leq 0 \), in which case it reverses the sign.

In case \( \kappa_1 \kappa_2 < 0 \), we actually have \( \hat{\mathcal{L}}_{\kappa_1}^{\kappa_2}(P, Q) \approx \hat{\mathcal{L}}_{-1}^{+1}(Q_1) \) with \( Q_1 \) as in the statement of (2.4). We leave the task of determining \( Q_0 \) in the other two cases to the interested reader.

Let us denote by \( \hat{U}_c, \hat{U}_d \) and \( \hat{T} \subset \hat{\mathcal{L}}_{-1}^{+1}(Q; \theta_1) \) the subspaces consisting of all condensed, diffuse and critical curves, where \( Q = (q, z), e^{i\theta_1} = z \) and \( \hat{\mathcal{L}}_{-1}^{+1}(Q; \theta_1) \)
consists of those curves in $\hat{\mathcal{L}}_{-1}^{-1}(Q)$ which have total turning $\theta_1$. The analogue of (3.3), stating that $\hat{\mathcal{U}}_c$ is either empty or contractible, is, naturally, (3.4), which was used to prove (3.3). The results and proofs in Section 4 all need minimal or no modifications. In particular, $\hat{\mathcal{U}}_d$ is always nonempty and weakly contractible.

The proof that $\partial\hat{\mathcal{U}}_d = \hat{T}$ is the same as the one given in (5.1). The proof that $\partial\hat{\mathcal{U}}_c = \hat{T}$, however, needs to be modified, since we have relied on (1.5). The idea is again to apply construction (3.8), but to all of $\gamma$, not just to some of its arcs as in the proof of (5.1). If $\gamma$ is a critical curve, then the corresponding function $f$ (see Figure 4) will attain the values $\pm\infty$, and at these points we need to assign weights, corresponding to the lengths of the line segments where $\theta_\gamma$ attains its maximum and minimum. Then we redefine $A(\mu_-, \mu_+)$ as the sum of the area under the graph of $f(\mu_-, \mu_+)$ plus the weight at $+\infty$ minus the weight at $-\infty$. The process described in (3.8) will transform $f$ into a bounded function of the same area; that is, it will decrease the amplitude of $\gamma$, making it a condensed curve.

The proofs of (3.17), (5.3) and (5.4), which deal with the existence of condensed and critical curves, go through unchanged; the only difference in the conclusions is that the corresponding regions $R_{\hat{\mathcal{U}}_c}$, $R_\sigma$ and $R_{\hat{T}}$ of the plane are now closed, instead of open. Thus, in the analogue of (6.1), the region of Figure 1 should contain the two circles of radius 2, but not the circle of radius 4, and we cannot assert that $\hat{\mathcal{U}}_c$ and $\hat{\mathcal{U}}_d$ are homeomorphic to $E$, only that they are weakly contractible. The rest of the statement and the proof hold without modifications.

Similarly, the version of (7.1) for $\hat{\mathcal{L}}_{\kappa_1}^{\kappa_2}(P, Q)$ states that this space has one contractible connected component for each realizable total turning when $\kappa_1\kappa_2 \geq 0$. The proof is the same as that of (7.1) if $\kappa_1\kappa_2 > 0$. If $\kappa_1 = 0$, then we cannot really parametrize $\gamma \in \hat{\mathcal{L}}_{\kappa_1}^{\kappa_2}(P, Q)$ by argument. Nevertheless, the proof still works if we replace $\rho(\theta)d\theta$ by a measure $\mu(\theta)$ on the Borel subsets of $[0, \theta_1]$ which has an atom at $\theta$ if the curvature of $\gamma$ vanishes at $\gamma(\theta)$; note that the convex combination of two measures is again a measure. The case where $\kappa_2 = 0$ can be deduced from this one by reversing orientations.

A few conjectures of Dubins. All of the results in the next proposition were conjectured by Dubins [1961, §6].

(9.2) Proposition. Let $q \in \mathbb{C}$, $\theta_1 \in \mathbb{R}$, $z = e^{i\theta_1}$ and $Q = (q, z)$. Then:

(a) The set of all $(q, \theta_1)\in \mathbb{C} \times \mathbb{R}$ such that $\hat{\mathcal{L}}_{-1}^{+1}(Q; \theta_1)$ is disconnected is a bounded subset of $\mathbb{C} \times \mathbb{R}$, neither open nor closed.\footnote{Actually, Dubins had guessed that this set would be bounded and open in $\mathbb{C} \times \mathbb{R}$.}

(b) $\hat{\mathcal{L}}_{-1}^{+1}(Q; \theta_1)$ has at most two components.
(c) If $\hat{L}^+_{-1}(Q; \theta_1)$ is disconnected, then one component ($\hat{U}_d$) contains curves of arbitrarily large length, while the supremum of the lengths of curves in the other component ($\hat{U}_c$) is finite.

(d) Every point of $\mathbb{C}$ lies in the image of some $\gamma \in \hat{U}_d$, while the images of curves in $\hat{U}_c$ are contained in a bounded subset of $\mathbb{C}$.

Proof. Parts (a) and (b) are immediate from the analogue of (6.1) for $\hat{L}$. As discussed above, $\hat{L}^+_{-1}(Q; \theta_1)$ is disconnected if and only if $|\theta_1| < \pi$ and $q$ lies in the region in Figure 1 including the circles of radius 2 but not the circle of radius 4. Suppose that $q$ does lie in this region. Choose $\hat{\omega} \in (\theta_1, \pi)$ such that

$$|q - \text{sign}(\theta_1) i (z - 1)| < 4 \sin\left(\frac{\hat{\omega}}{2}\right).$$

Then (5.6) implies that there does not exist any curve in $\hat{L}^+_{-1}(Q; \theta_1)$ having amplitude in $[\hat{\omega}, \pi]$. The assertions about $\hat{U}_c$ in (c) and (d) now follow from (3.15).

The assertions about $\hat{U}_d$ are obvious, because, by (the version for $\hat{L}$ of) (4.18), this subspace always contains curves of amplitude $\geq 2\pi$, and onto such a curve we may graft line segments of any direction and arbitrary length. □

As expected, there is a version of the foregoing proposition for $L^+_{-1}(Q; \theta_1)$. The corresponding assertions in (a) and (b) are immediate from (6.1), and the assertions about $L_d$ are again obvious. A curve in $L_c$ parametrized by arc-length can also be considered as an element of $\hat{U}_c$, so the properties stated in (c) and (d) for $L_c$ follow from those for $\hat{U}_c$ unless $q$ lies on the circle of radius 4 in Figure 1. In this case, $L^+_{-1}(Q; \theta_1)$ is disconnected, but $\hat{L}^+_{-1}(Q; \theta_1)$ is not. One can prove directly that the length of any $\gamma \in L_c$ must be smaller than that of the “canonical” critical curves of type $+-$ or $-+$ that were constructed in the proof of (5.3).

Conjectures on minimal length. Let $L(\gamma)$ denote the length of $\gamma$ and suppose that $\hat{L}^+_{-1}(Q; \theta_1)$ is disconnected. We believe that the results developed here may be used to prove that if $m = \sup_{\gamma \in L_c} L(\gamma)$ and $M = \inf_{\gamma \in \hat{U}_d} L(\gamma)$, then $m < M$; this is another conjecture of Dubins. It would be interesting, and probably useful for applications, to find the values corresponding to $m$ and $M$ for the more general spaces $\hat{L}^+_k(Q)$.

We observed in (2.5) that normal translations, and hence the homeomorphisms of (9.1) need not preserve inequalities between lengths. Since they do map circles to circles and lines to lines, it could still be expected that the image of a curve which minimizes length under these homeomorphisms is likewise of minimal length. Unfortunately, this is false. Suppose, for instance, that we apply the homeomorphism $\hat{L}^+_{-1}(Q) \to \hat{L}^+_1(Q_0)$ to the Dubins path in Figure 3(b). It should be clear that its image, which again consists of a line segment and two arcs of circles of opposite orientation with the same amplitude as before, does not minimize
length in $\hat{L}^1_{100}(Q_0)$, since in the latter space it is generally much more efficient to curve to the left than to the right, even if this yields a path of greater total turning.

In spite of this difficulty, we conjecture that Dubins’ theorem that any shortest path in $\hat{L}^{+\kappa_0}_{-\kappa_0}(P, Q)$ must be a concatenation of three pieces, each of which is either an arc of circle or a line segment, still holds for the spaces $\hat{L}^{k_2}_{k_1}(P, Q)$, $\kappa_1\kappa_2 < 0$. For $\kappa_1\kappa_2 > 0$, we conjecture that a curve of minimal length is a concatenation of $n$ arcs of circles of curvature $\kappa_1$ and $\kappa_2$. However, for fixed $P, Q \in UT \mathcal{C}$, we must have $\lim_{\kappa_1, \kappa_2 \to +\infty} n = \infty$. Indeed, a curve of this type has total turning at most $2n\pi$, and the minimal total turning of a curve in $\hat{L}^{k_2}_{k_1}(Q)$ increases to infinity as $\kappa_1 > 0$ increases to infinity (for fixed $Q = (q, z)$ with $q \neq 0$).
